Outline

- Background
 - Glucose-insulin regulation
- Provocation Experiments
 - Intravenous glucose tolerance test (IVGTT)
 - Oral glucose tolerance test (OGTT)
- Model Building
 - Intravenous Provocation Experiments
 - Overview: Previous modeling of the system (IVGTT)
 - Structural model
 - Feedback loops
 - Combined IV and Oral Provocation Experiments
 - Glucose absorption (OGTT)
- Results and Discussion
- Conclusion and Future Applications

UPPSALA
UNIVERSITET

Glucose–Insulin System

Pharmaceuticals

Liver

Pancreas

High blood glucose inhibits glucose release from the liver

Glucose

High blood glucose promotes insulin release

Insulin stimulates glucose uptake from blood

Insulin

Blood Circulation

Glucose elimination

Tissue Cells

Insulin elimination

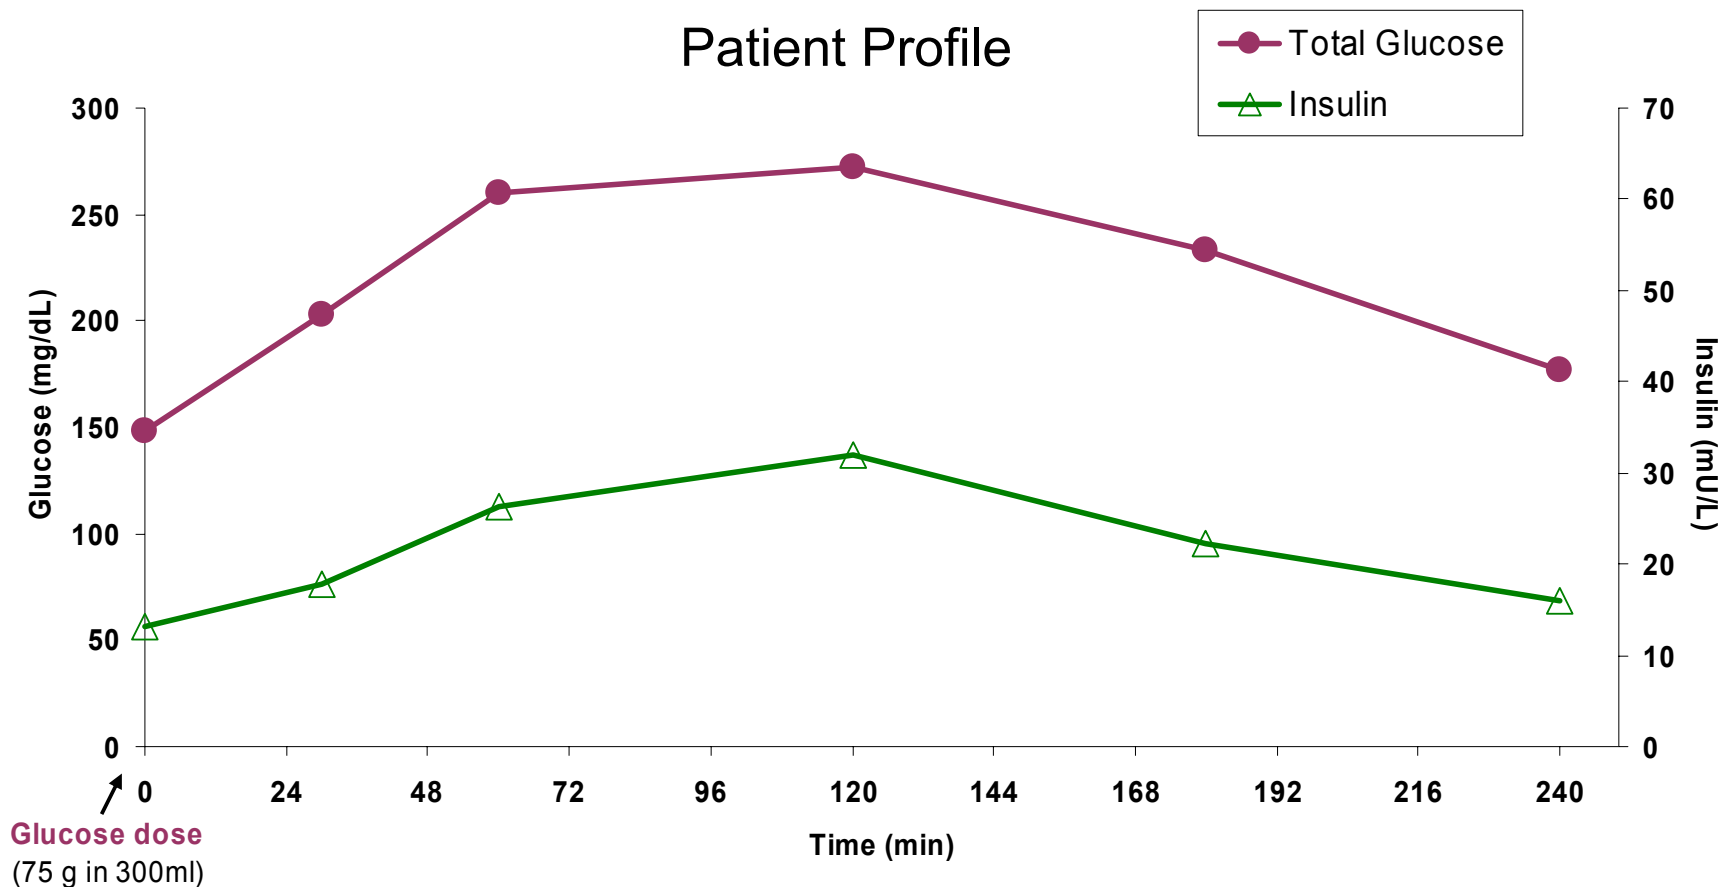

IVGTT - Intravenous Glucose Tolerance Test

Patient Profile

OGTT- Oral Glucose Tolerance Test

Modeling of the Glucose–Insulin System

1979 1980

Minimal Model (Bergman et al)

- One-compartment model for glucose
- Conditioned on observed insulin
- Individual data analysis

Similar models were built for insulin conditioned on observed glucose
(e.g. Toffolo et al)

2000 2001

Joint Glucose-Insulin Model (DeGaetano et al)

- One-compartment model for glucose and insulin
- Individual data analysis

Two-Compartment Minimal Model (Vicini et al)

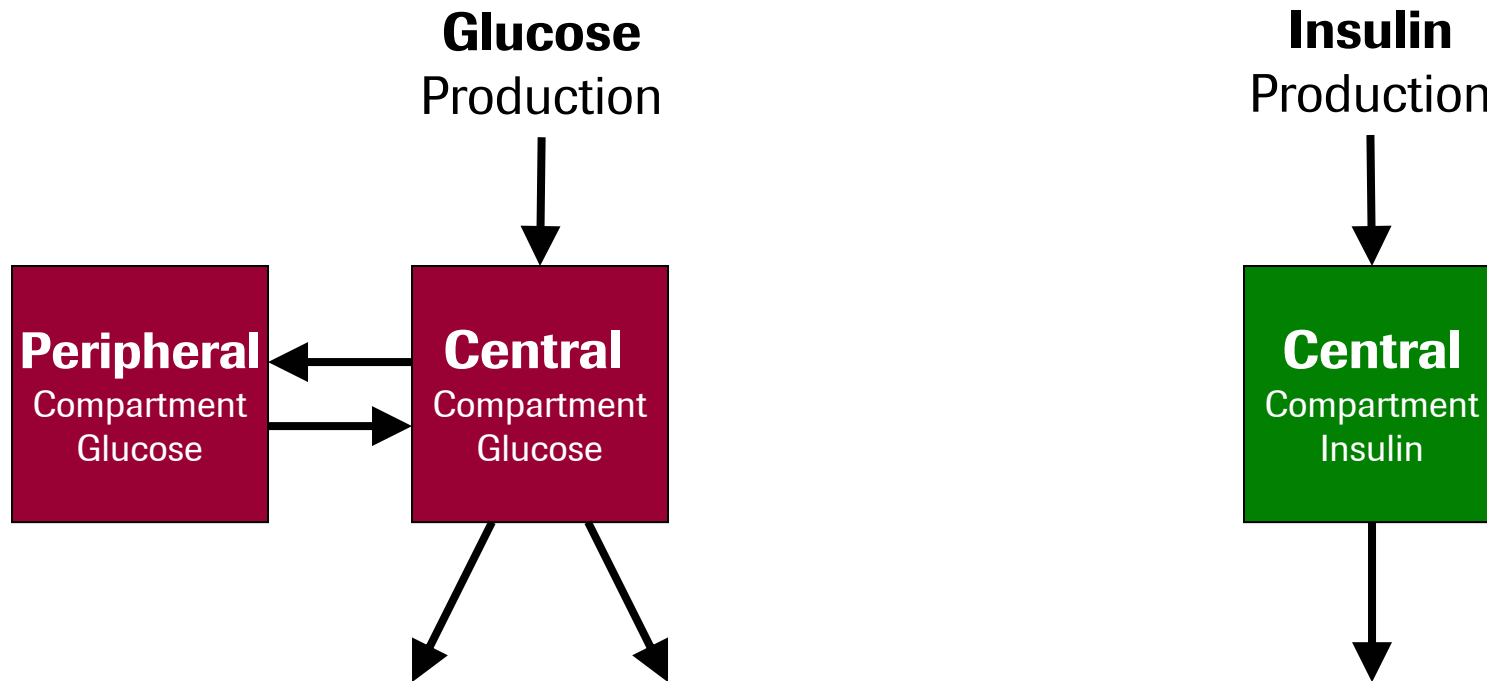

- Population data analysis
- Labeled glucose

A simultaneous model for glucose AND insulin is necessary for adequate simulations. Addressing several types of provocations in healthy volunteers and patients would be desirable.

Study Protocol and Data for the Development of the IV Model

	Type	Subjects	Insulin infusion	Labeled Glucose
Study 1	IVGTT	14 healthy volunteers	-	Yes
Study 2	IVGTT	42 patients	Short infusion at t = 20 min	Yes
Study 3	Clamp	6 healthy volunteers	Continuous	Yes
Study 4	IVGTT	10 healthy volunteers	Short infusion at t = 20 min	Yes

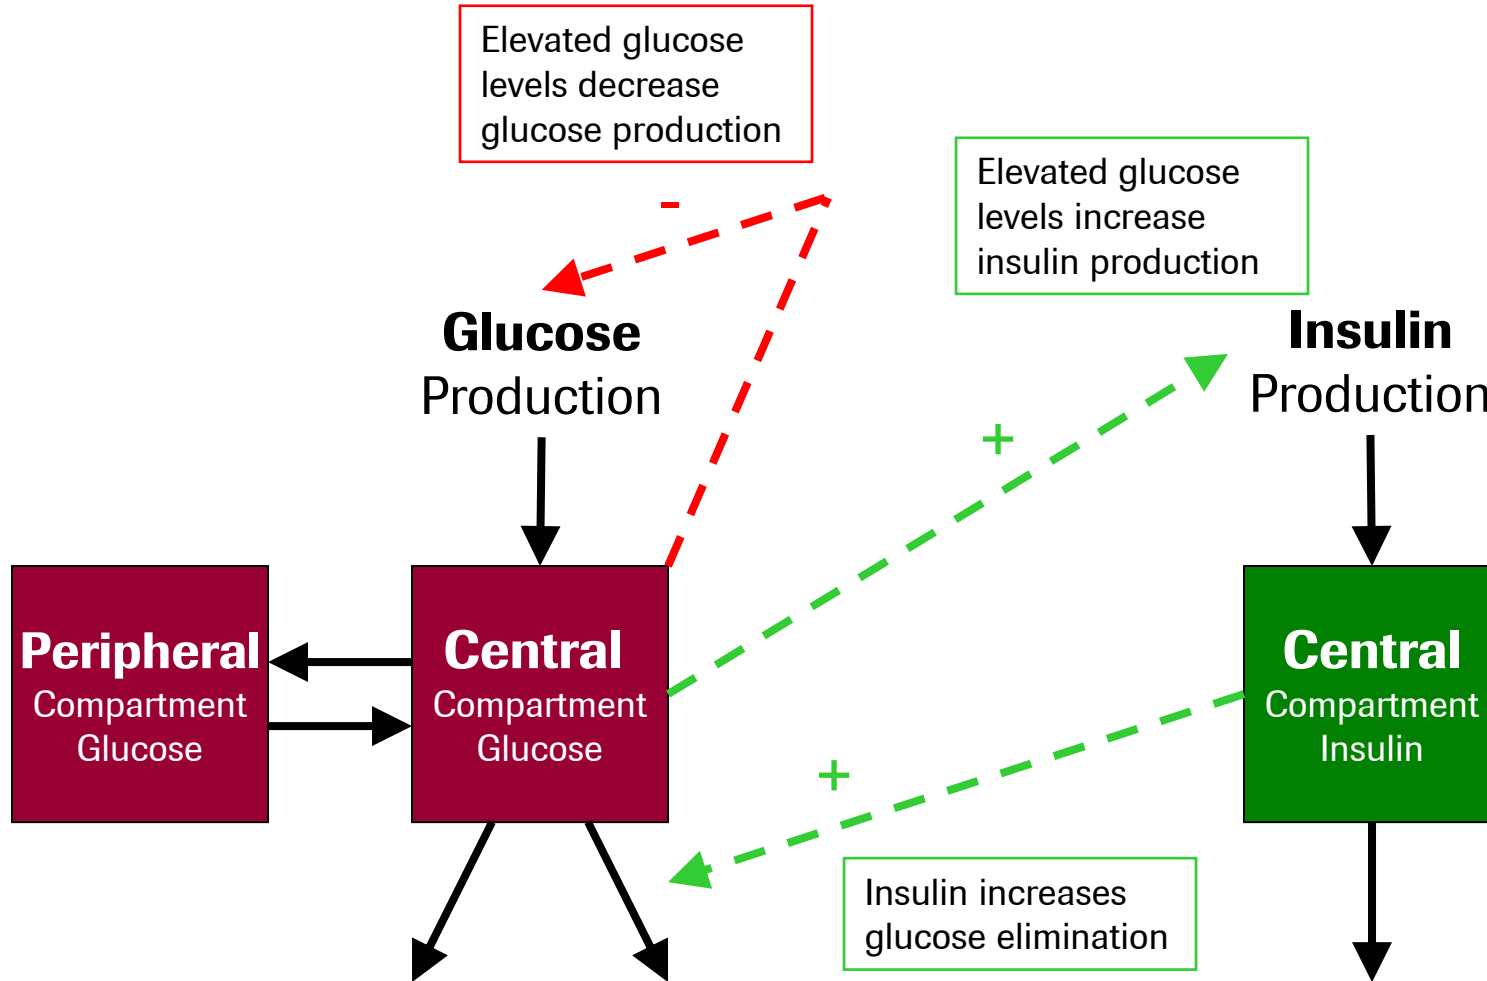

Model Building – First Steps (IV only)

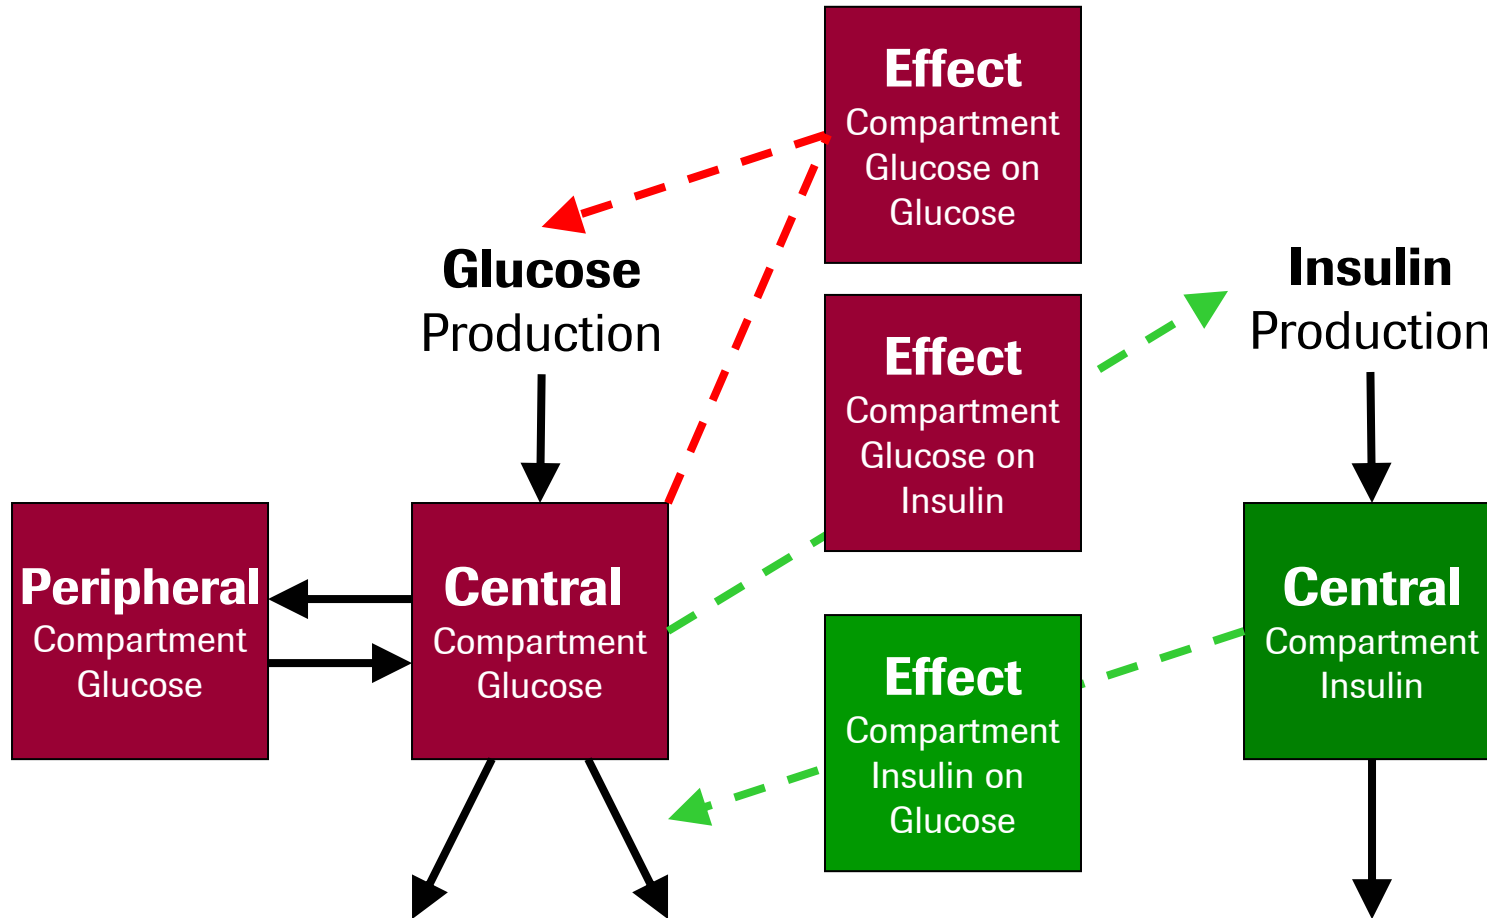

Feedback Mechanisms and Interactions

Between Glucose and Insulin in **Hyperglycemic** Condition

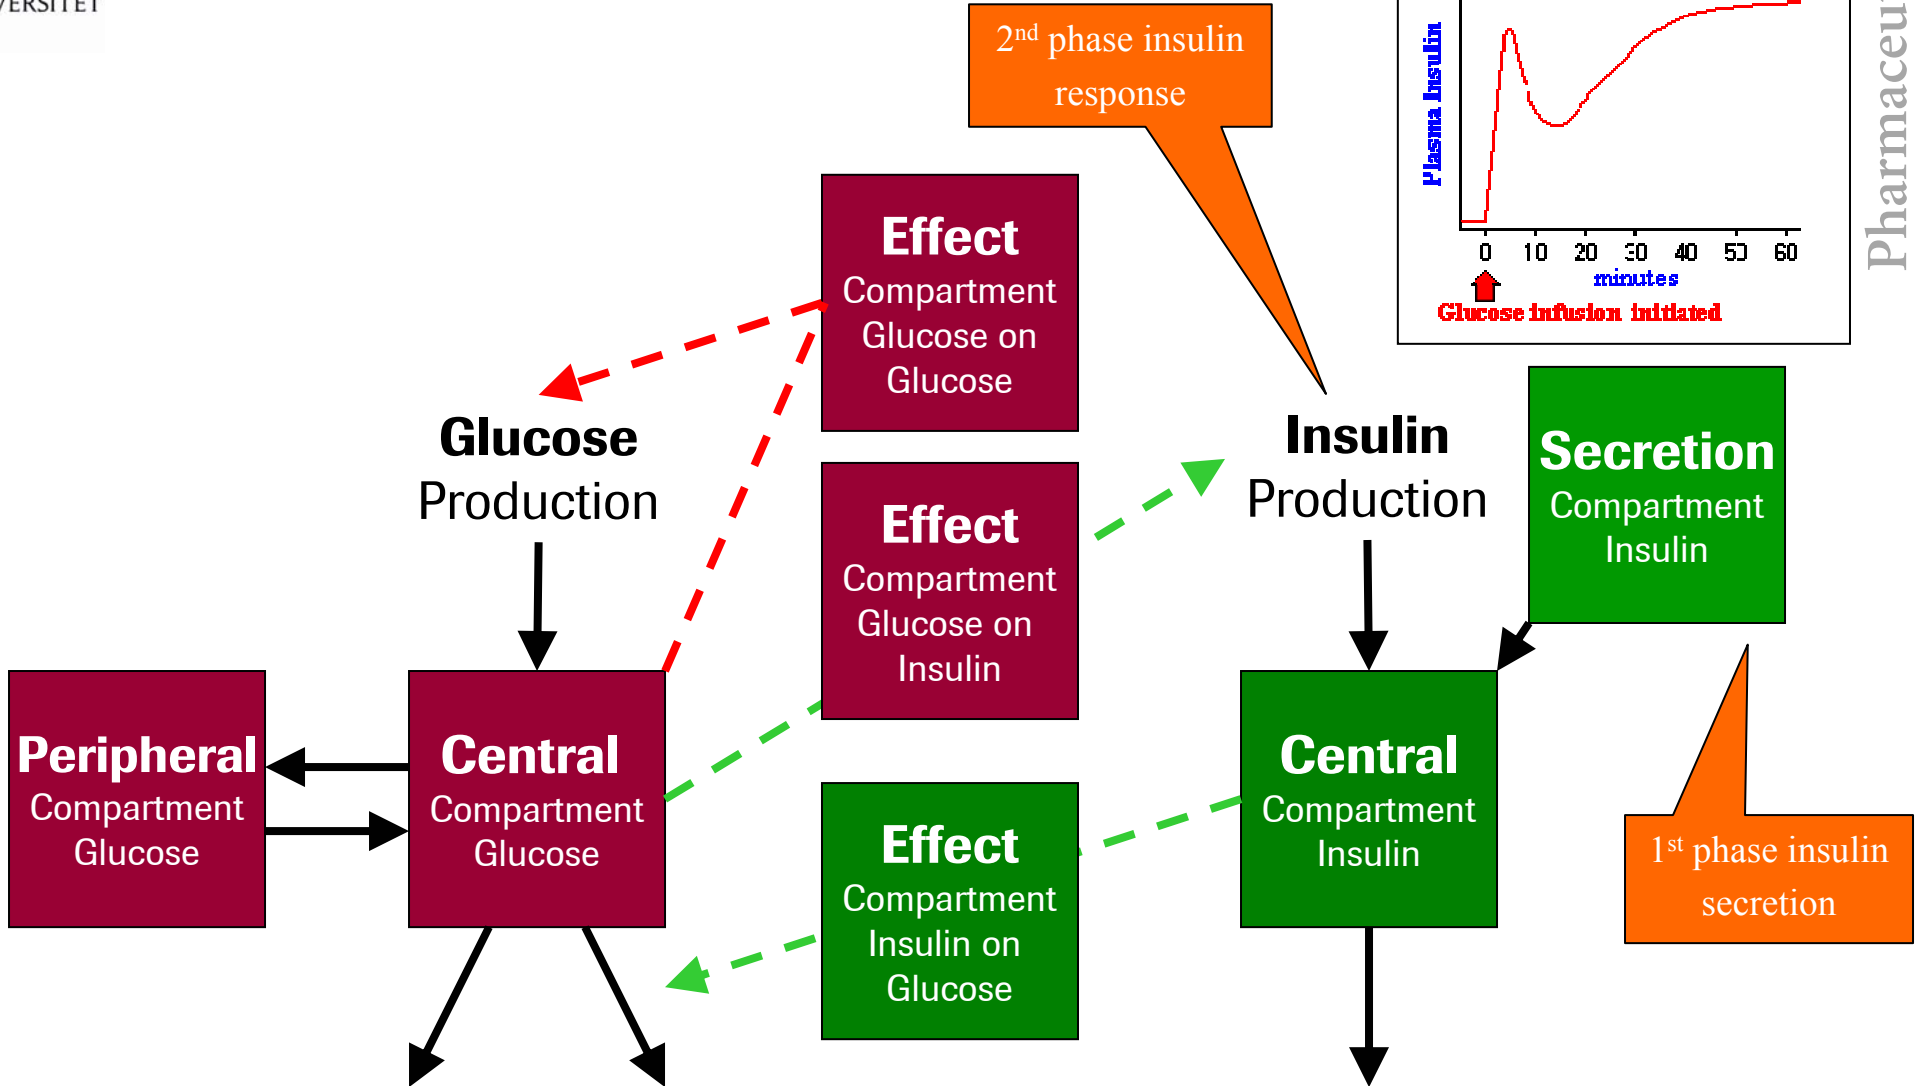

Effect Compartments

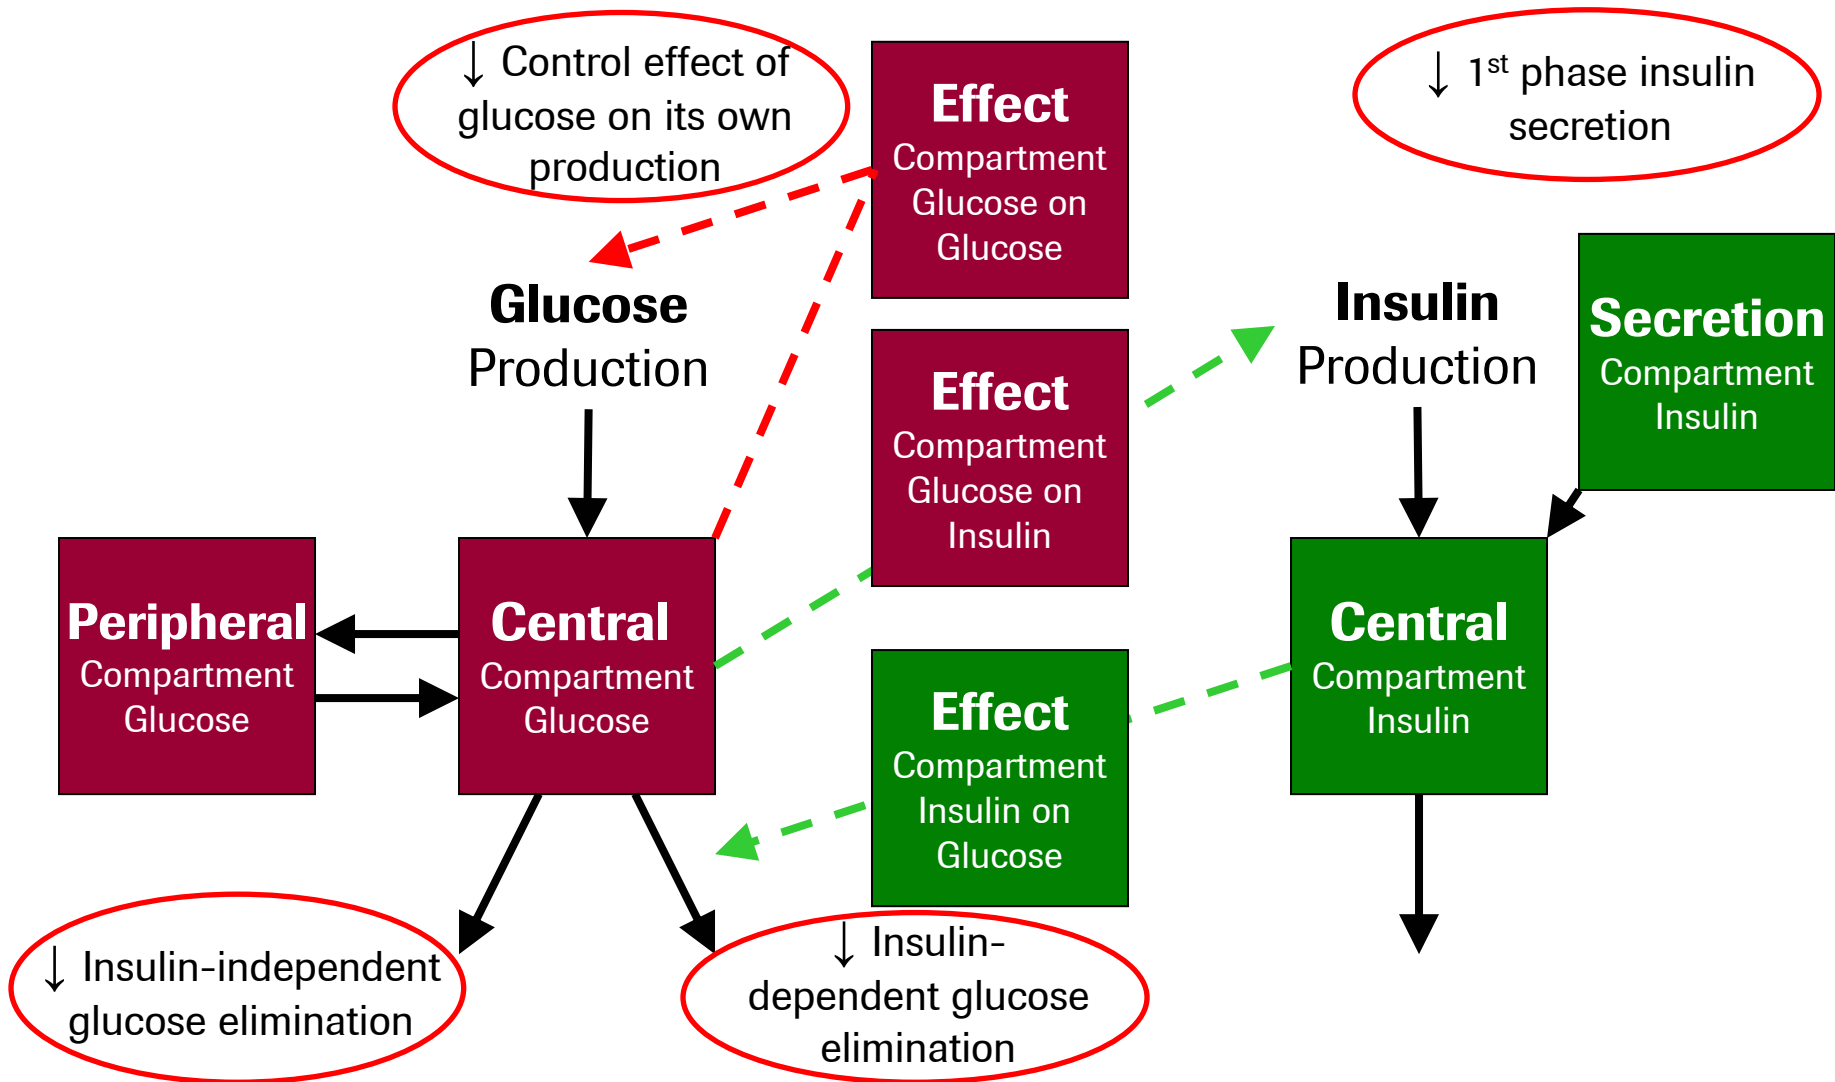

Insulin Secretion

Final IV Model

Parameter Differences in Patients Compared to Healthy Volunteers

Study Protocol and Data for the Development of the Combined Model

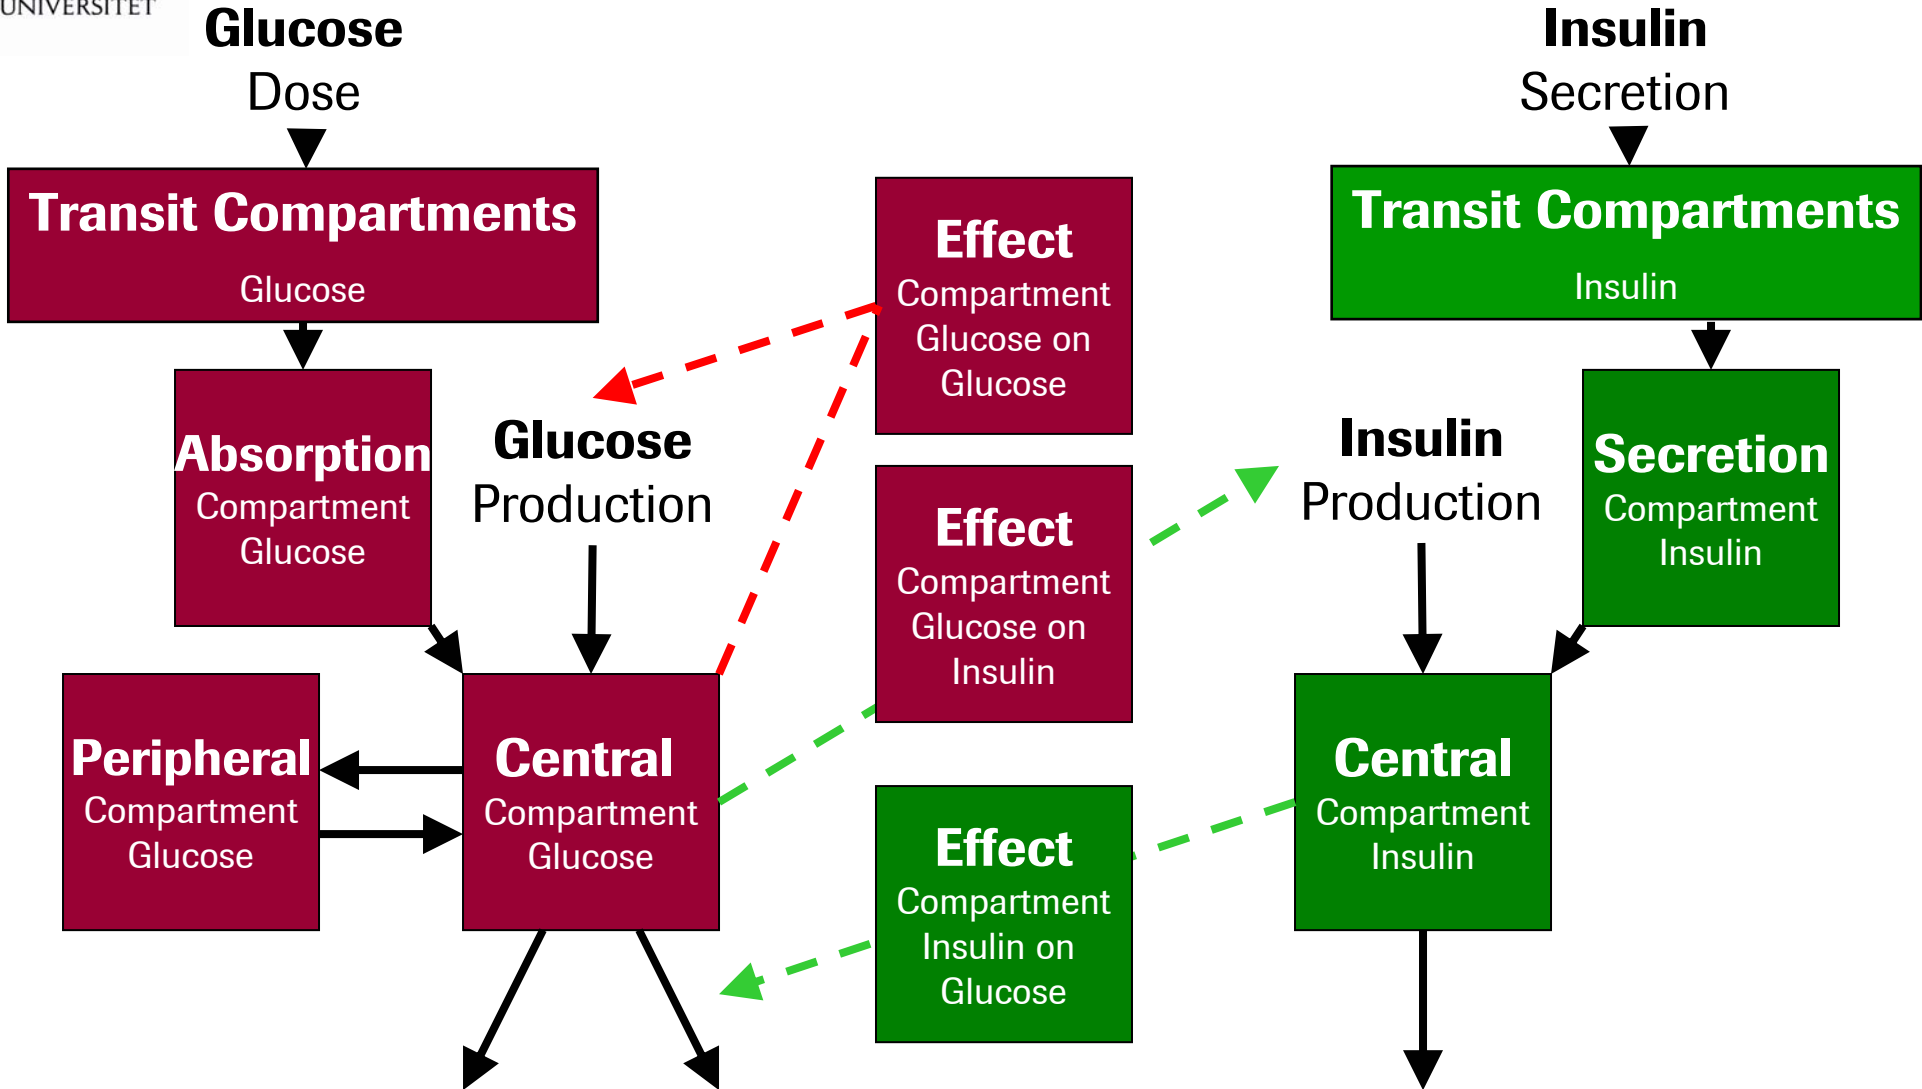

All data from **type 2 diabetic patients**

IVGTT and OGTT performed in the same 42 subjects

Type	Dose	Number of samples	Insulin infusion	Labeled Glucose
IVGTT	300 mg/kg	34 within 4 hours	Short infusion at t = 20 min	Yes
OGTT	75 g	6 within 4 hours	-	No

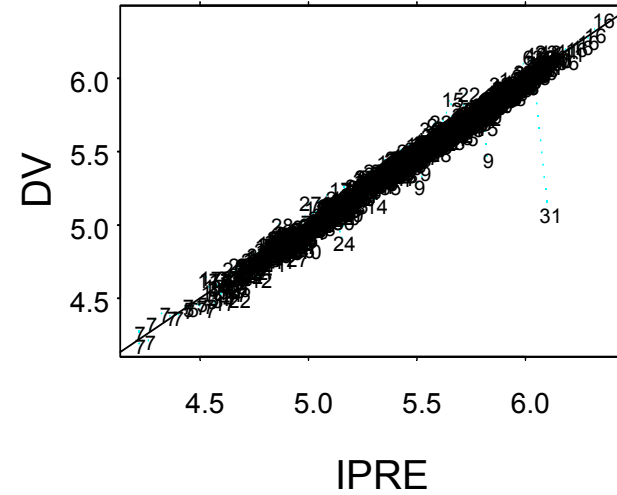

Model Adaptation to OGTT

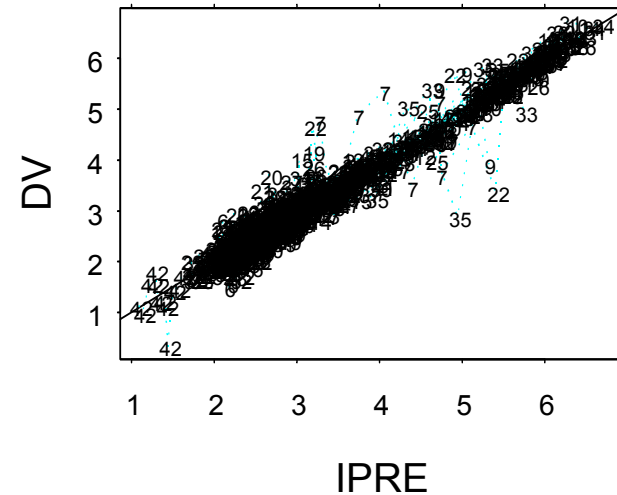

Goodness of Fit Plots IVGTT

Glucose

Insulin

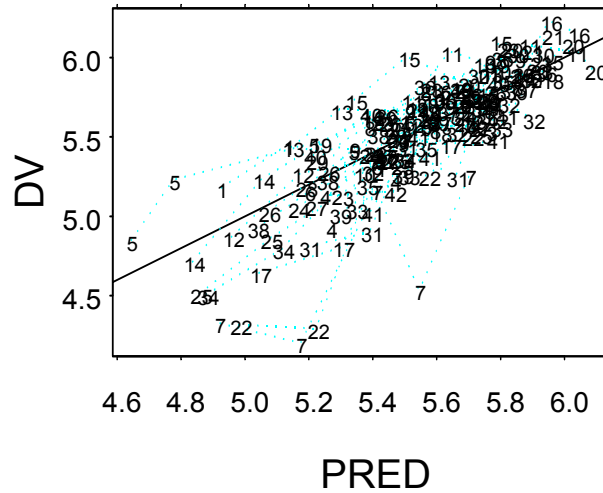

Goodness of Fit Plots OGTT

Glucose

Insulin

Simulations

Glucose IV

Insulin IV

Glucose ORAL

Insulin ORAL

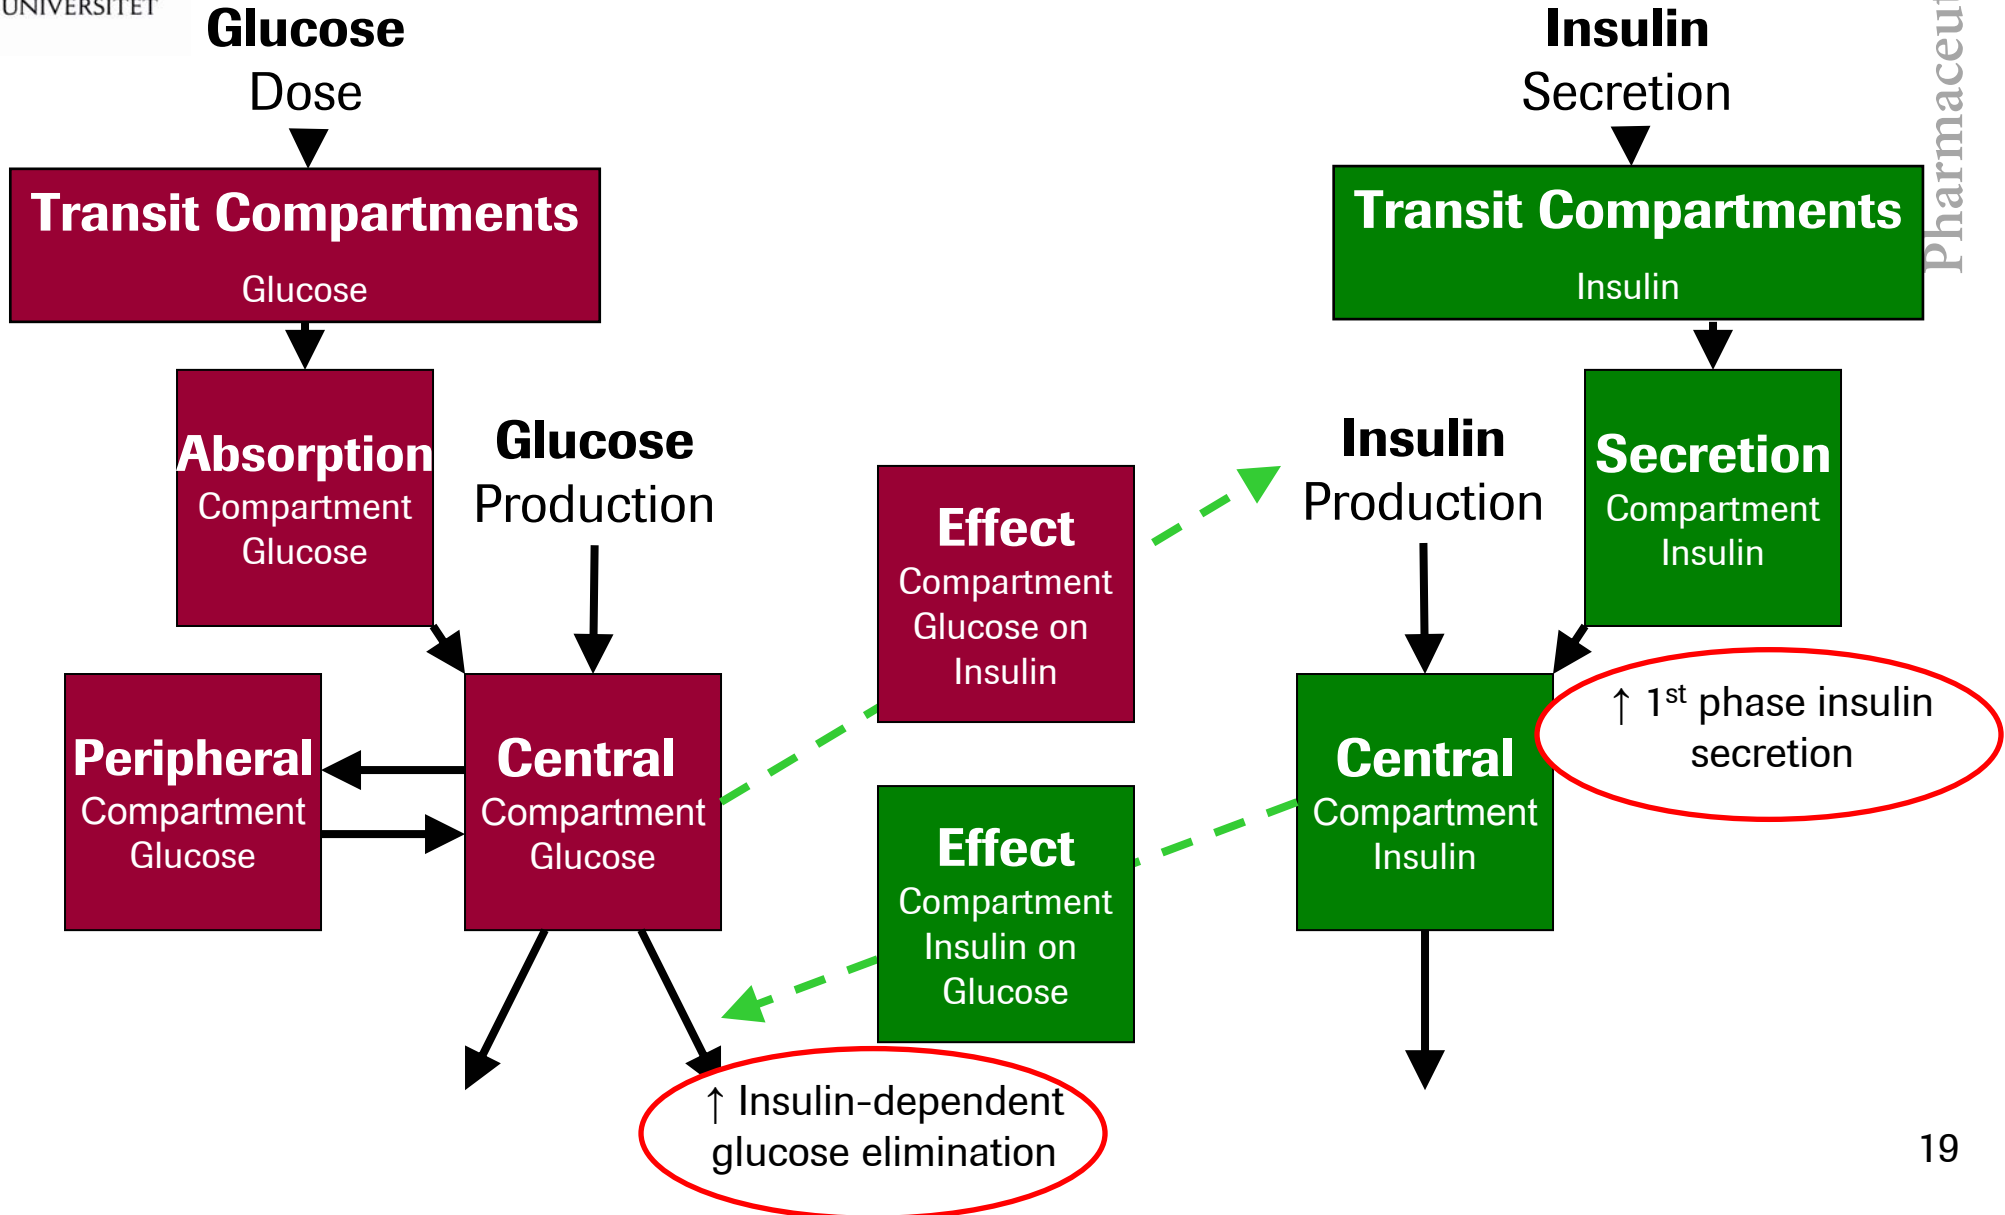

Result Summary

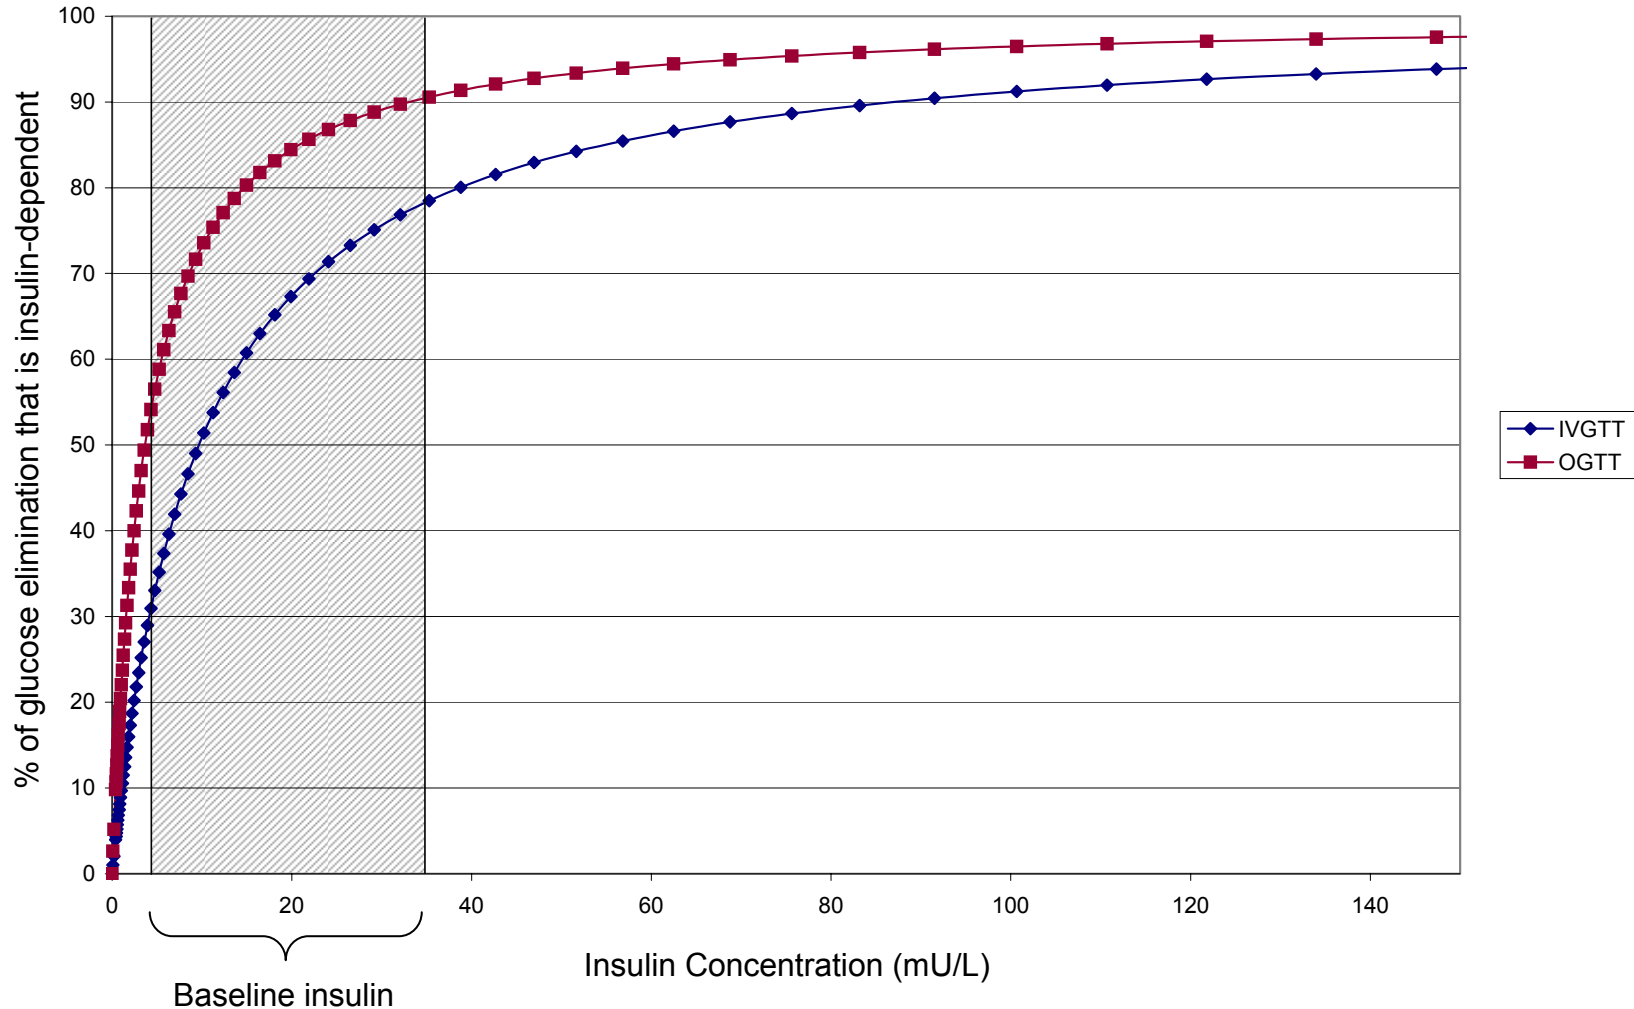

- Model described OGTT data well
- Absorption phase of glucose adequately described, bioavailability estimated to approximately 80%
- Parameters well estimated ($CV < 15\%$ for all parameters except absorption rate constant)
- Residual errors (multiplicative):
 - Glucose: 5% CV (IVGTT) and 8% CV (OGTT)
 - Insulin: 25% CV (both IVGTT and OGTT)
- Adequate simulations of glucose and insulin concentration-time profiles

Final Combined IV and PO Model

Parameter Differences in OGTT Compared to IVGTT in Patients

Percentage of Insulin-Dependent Glucose Elimination in IVGTT and OGTT

Differences Between IVGTT and OGTT

- Significant first-phase insulin secretion after OGTT
 - Related to the release of the insulin secretagogue GLP-1 (glucagon-like peptide-1) from the gastrointestinal tissues
 - potentiating effect on insulin secretion
 - Higher glucose dose given in the OGTT
- Higher insulin-dependent glucose elimination after OGTT (~3 fold)
 - Similar factor observed for insulin sensitivity in previous works. May be due to gastrointestinal or first-pass effects enhancing insulin sensitivity in the liver or the muscle tissue – under debate
 - Impact of the insulin infusion in the IVGTT ?

Conclusion and Future Applications

Achieved: Integrated model for glucose and insulin following OGTT and IVGTT, addresses two different routes of administration simultaneously

Future Aims:

- Evaluation of the model by applying it to a different patient population (more severe disease, Type 1 diabetics etc.)
- Explore possible covariate influence (severity of disease, treatment duration)
- Extension of the model to meal test data
- Study design optimization
- Implementation of drug effects (e.g. PPAR, SU...)
