30/06/2022

# Context

Start of the COVID-19 pandemic

Thousands of cases

Saturation of intensive care units and emergency departments

- **Personalized predictions** of the survival of hospitalized patients for SARS-COV-2 infection can be useful:
  - To streamline therapeutic alternatives (escalation or limitation of care)
  - To improve hospital organization (beds, staff...) and forecast needs

# Context

Start of the COVID-19 pandemic

Thousands of cases

Saturation of intensive care units and emergency departments

- **Personalized predictions** of the survival of hospitalized patients for SARS-COV-2 infection can be useful:
    - To streamline therapeutic alternatives (escalation or limitation of care)
    - To improve hospital organization (beds, staff...) and forecast needs
  - Since 2020, prognostic **scores**<sup>1,2,3</sup> have been developed using clinical characteristics available at hospital admission
- 4C-score**<sup>1</sup> includes baseline characteristics (age, gender, comorbidities) and baseline biomarker measurement (admission CRP, urea,...)

1- Knight et al., *BMJ*, 2020  
 2- Myrstad et al., *Scand J Trauma Resusc Emerg Med*, 2020  
 3- Liang et al., *JAMA Intern Med*, 2020

## Context

- **Clinical studies** described association between prognosis and baseline biomarker measurements<sup>4,5,6</sup>, or biomarkers changes between different days<sup>7,8,9</sup>

**Mueller et al.** Inflammatory Biomarker Trends Predict Respiratory Decline in COVID-19 Patients, *Cells Reports Medicine*, 2020

# Context

- **Clinical studies** described association between prognosis and baseline biomarker measurements<sup>4,5,6</sup>, or biomarkers changes between different days<sup>7,8,9</sup>

**Mueller et al.** Inflammatory Biomarker Trends Predict Respiratory Decline in COVID-19 Patients, *Cells Reports Medicine*, 2020

- None of them consider **the full** follow-up of biological information until clinical outcome

## Objectives:

- To build a multivariable joint model with several biomarkers most associated with the risks of in-hospital death / discharge from hospital
- To assess the added value of considering results of biological exams during stay compared to only baseline (admission) information

4- Zhang et al., *J Thromb Haemost*, 2020  
 5- Zhu et al., *BMC Infect Dis*, 2020  
 6- Tjendra et al. *Arch Pathol Lab Med*, 2020

 8- Lavillegrand et al. *Ann Intensive Care*, 2021  
 9- Mueller et al. *Cell reports Medicine*, 2020

## Patients

- Retrospective cohort (RisCOV, PI: Pr Xavier Lescure)
  - 327 patients
  - 59 biomarkers
- Patients hospitalized during the **first wave of COVID-19 pandemic** (January to July 2020) in the Infectious and Tropical Disease Department of Bichat AP-HP (Paris, France)
- An extraction of the AP-HP data warehouse provided all the results of **available biological exams** during hospital stay until day 30
- Manual data collection for **clinical variables** and outcomes at day 30

## Outcomes

- **Time to in-hospital death** (event of interest)
- **Time to discharge from hospital** (competing event)

# Survival data

Cumulative incidence functions (CIF) for in-hospital death and discharge from hospital

$N = 327$  patients

Median follow-up time : 7.7 days

**30 days after admission**

Deaths – Number (%)	46 (14%)
Discharges – Number (%)	238 (73%)
Censoring – Number (%)	43 (13%)
Hospital transfer	20 (6%)
Still hospitalized at D30	23 (7%)

<b>Nb deaths</b>	0	9	23	30	39	44	46
<b>Nb discharges</b>	0	48	137	191	220	227	238
<b>Nb censoring</b>	0	4	12	14	16	19	20
<b>Nb at risk</b>	327	266	155	92	52	37	23

## Biomarker data

$N = 327$

$K = 59$

3

# Multivariable analysis

Biomarkers selected at the previous step are grouped following the initial classification

For each group, the biomarker with the **most significant** p-value for  $\alpha_{1k}$  is considered for the multivariable analysis

## Backward selection (for the risk of in-hospital death)

Removed the highest p-value Wald test for  $\alpha_{1k}$

Stop when all p-values for  $\alpha_{1k} < 5\%$

## Backward selection (for the risk of discharge from hospital)

Removed the highest p-value Wald test for  $\alpha_{2k}$

Stop when all p-values for  $\alpha_{2k} < 5\%$

## Statistical methods

### Model estimation

- Estimation by maximization of the likelihood (SAEM algorithm, Monolix 2018R2)

### Individual predictions

- Derivation of dynamic predictions<sup>10,11</sup> given 3 landmark times: D3, D6, D9
- Performances assessment using time-dependant AUC<sup>12</sup> and comparison with the baseline model

### Baseline model

$$\lambda_{1i}(t) = h_1 \times \exp(\beta_1 \times Score_i) \quad \longleftarrow \text{Subdistribution hazard for in-hospital death}$$

$$\lambda_{2i}(t) = h_2 \times \exp(\beta_2 \times Score_i) \quad \longleftarrow \text{Subdistribution hazard for discharge from hospital}$$

- Baseline score = 8
- Discharged at day 24

Survival prediction at day 30:  
0.90 (95% CI [0.87,0.93])

### Patient B

- Baseline score = 6
- Dead at day 22

Survival prediction at day 30:  
0.95 (95% CI [0.93,0.97])

# Individual *dynamic predictions*

Patient A, baseline score = 8, discharged at day 24

- landmark time
- future marker value
- observed marker value
- predicted pH value
- predicted CRP value
- predicted neutrophil value
- predicted survival
- death
- discharge
- 95% prediction interval

# Individual dynamic predictions

Patient B, baseline score = 6, dead at day 22

- landmark time
- future marker value
- observed marker value
- predicted pH value
- predicted CRP value
- predicted neutrophil value
- predicted survival
- death
- discharge
- 95% prediction interval

# Prediction performances

## Time-dependant AUC for baseline and multivariable joint model

Horizon time = 30	Landmark day 3
AUC [95% CI] – baseline model	0.79 [0.72,0.86]
AUC [95% CI] – joint model	0.82 [0.75,0.89]
p-value	0.37

# Prediction performances

## Time-dependant AUC for baseline and multivariable joint model

Horizon time = 30	Landmark day 3	Landmark day 6
AUC [95% CI] – baseline model	0.79 [0.72,0.86]	<b>0.73</b> [0.65,0.81]
AUC [95% CI] – joint model	0.82 [0.75,0.89]	<b>0.81</b> [0.73,0.89]
p-value	0.37	<b>0.04</b>

# Prediction performances

## Time-dependant AUC for baseline and multivariable joint model

Horizon time = 30	Landmark day 3	Landmark day 6	Landmark day 9
AUC [95% CI] – baseline model	0.79 [0.72,0.86]	<b>0.73</b> [0.65,0.81]	<b>0.64</b> [0.55,0.74]
AUC [95% CI] – joint model	0.82 [0.75,0.89]	<b>0.81</b> [0.73,0.89]	<b>0.84</b> [0.75,0.93]
p-value	0.37	<b>0.04</b>	<b>&lt;10<sup>-5</sup></b>

## Discussion

- We showed the added-value of **longitudinal biological follow-up** and the joint modelling approach for improving prognosis predictions.
- The originality of the work relies on:
  - the statistical approach combining multiple longitudinal models jointly estimated with a parametric subdistribution model
  - the use of real-life hospital data to collect massive data on biological examinations
- Such a tool could help clinicians in **complex decisions** such as therapeutic escalation or limitation of care (which arise during the follow-up and not at admission)

## Discussion

- We showed the added-value of **longitudinal biological follow-up** and the joint modelling approach for improving prognosis predictions.
- The originality of the work relies on:
  - the statistical approach combining multiple longitudinal models jointly estimated with a parametric subdistribution model

- Such a tool could help clinicians in **complex decisions** such as therapeutic escalation or limitation of care (which arise during the follow-up and not at admission)

### Limits

- No correlation was tested between parameters
- Performances should be evaluated on an external data set
- In high dimension, stepwise/backward selection on regression models have been shown to be outperformed by penalized regression methods<sup>13,14</sup>

Perspective: a **LASSO penalization**<sup>13</sup> implementation
