

Background

- Nonparametric (NONP) models are an attractive alternative to parametric models, especially when data arise from different sub-populations
- However, methodology¹ for screening covariates given discrete distribution of model parameters is limited in scope and no convenient statistical test can be applied to discriminate between competing NONP models

Objectives

To develop a new covariate modeling approach adjusted for nonparametric parameter distributions

To evaluate the performance of the method when based on FOCE-NONP parameter estimates in NONMEM in terms of:

- Type-I error rate of covariate inclusion
- Statistical power
- Bias/Imprecision in regression estimates

Method principle

A Perl script automates the 3-step process involving NONMEM, PsN², and GAM package in R³

Hypothesis: Is Age an informative predictor of CL given the NONP structural model?

Graphical example:
Gaussian population J = 5 IDs
Continuous covariate (e.g. Age)

NONMEM
→ NONP estimation

Step 1: Obtain individual probability densities (IPDs) = Marker of dependency between support points

PsN
(NONP subroutine)

PsN output: JxJ unique IPDs

Step 2: Second-stage regression model of covariates on support points given IPDs

R
(GAM package)

Regression by weighted GAM

$$CL_i = f(AGE_i) + \varepsilon_i * h(IPD_{ik})$$

$$h(IPD_{ik}) = IPD_{ik} \quad (1)$$

$$h(IPD_{ik}) = IPD_{ik} \times \left(1 - \frac{\text{var}(IPD_{ik})}{\text{var}(NPD_k)}\right) \quad (2)$$

Two weighting functions h can be considered, (2) being designed for sparse data to account for η -shrinkage

* Regression plan represents a weighted linear regression CL = AGE

Step 3: Calibration of the covariate method

→ **Aim:** Obtain a likelihood-based statistical criterion ($AIC_{perm,0.05}$) for decision-making

R
(GAM package)

1000 permutation tests + weighted GAMs

H0: $\beta = 0$
H1: $\beta \neq 0$
with P-value calibrated to user-defined value ($\alpha=0.05$)

Decision rule:
if $AIC_{perm} < AIC_{perm,0.05}$
Age significant predictor of CL

NONMEM (\$NONP)
with Age on CL

Hypothesis-testing scenarios

PK Model:

one-compartment: random effect on CL, V (30% CV), RV (10% CV)

Simulated Data:

- informative data (3 DVs/ ID, 100 IDs)
- 1000 simulated datasets per hypothesis-testing scenario (NM 6.2)

8 hypothesis-testing scenarios:

- continuous covariate: CL ~ f(AGE) - Correlation strength: $\beta_{true} = \{0, -0.006, -0.008, -0.010\}$
- categorical covariate: CL ~ f(SEX) - Correlation strength: $\beta_{true} = \{0, -0.150, -0.175, -0.200\}$

Estimates of statistical power & type-I error rate of covariate inclusion:

- apply stochastic simulation followed by estimation (SSE) subroutine in PsN
- apply nonparametric covariate method by weighted GAM on each dataset
- reference methodology = parametric covariate modeling by likelihood ratio tests (LRTs)

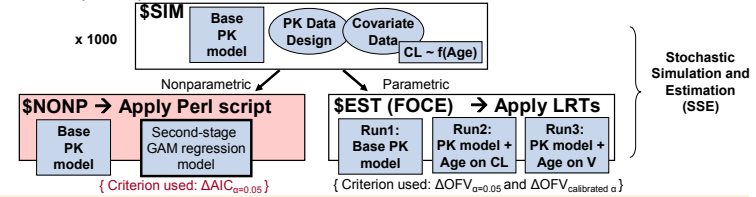

Figure 1. Hypothesis-testing scheme for computation of statistical power & type-I error rate of covariate inclusion (Age on CL) for both parametric and nonparametric PK models (scenarios 1 to 4 with varying β_{true})

Results

Scenario Number	Covariate Type	β_{true}	Tests	Criteria	Type-I error (α)	Statistical Power	$\hat{\beta}$	ME ($\hat{\beta}$)	RMSE ($\hat{\beta}$)
1	0		LRT (FOCE)	$\Delta OFV_{nominal \alpha=0.05}$	6.8%(CL) / 6.1%(V)	0	$< 10^{-3}$	$< 10^{-3}$	$< 10^{-3}$

(1) ΔAIC obtained with a weighting function h accounting for IPDs only – Similar estimates were obtained with (2) (data not shown)

Table 1. Estimates of type-I error rate and statistical power for covariate inclusion on CL obtained with LRT and the proposed covariate methodology. Estimates of regression coefficients $\hat{\beta}$, MEs and RMSEs are also displayed

Type-I error rate:

- Adequate calibration of the NONP covariate methodology (close to $\alpha=5\%$)
- Asymptotically approaching $\alpha=5\%$ as No. of SSE samples increases (data not shown)
- LRT: actual type-I error rate inflated compared to nominal α

Statistical power:

- Similar performance as LRT for Gaussian data

Regression estimates:

- Little bias (MEs) and similar imprecision (RMSEs) as LRT

Conclusions

A new, calibrated, covariate identification technique intended for nonparametric PKPD models is available

It presents as good statistical and estimation properties as LRT for Gaussian type-data regardless of the characteristics of the relationship and of the covariate distribution of interest

Although computationally demanding, this approach presents the advantage of not relying on nominal P-value and benefits from the robust framework of nonparametric data analysis
