

Evaluation of assumptions underpinning pharmacometric models

Qing Xi Ooi¹, Daniel Wright¹, Geoffrey Isbister², Stephen Duffull¹

¹ School of Pharmacy, University of Otago, Dunedin, New Zealand

² School of Medicine and Public Health, The University of Newcastle, Newcastle, Australia

Models and assumptions

- All models are underpinned by assumptions
- The validity of model inference depends on:
 - Probability
 - Impact of assumption violation
- The boundary beyond which the use of an assumption is invalid → limitation

Importance of assumption evaluation

Guidance for Industry Population Pharmacokinetics

Good Practices in Model-Informed Drug Discovery and Development: Practice, Application, and Documentation

EFPIA MID3 Workgroup et al., *CPT Pharmacometrics Syst Pharmacol.* 2016;5(3):93-122

Other published guidelines

Inadequate reporting of assumptions

- Assumptions are not addressed routinely in published literature
- Regulatory perspective (EMA/EFPIA M&S workshop in 2011):
 - Limitation of analysis submitted for regulatory review
 - A lack of transparent description of influential assumptions
- Barrier for effective model use and regulatory review

EFPIA MID3 Workgroup et al., CPT Pharmacometrics Syst Pharmacol. 2016;5(3):93-122

Existing framework

Aim

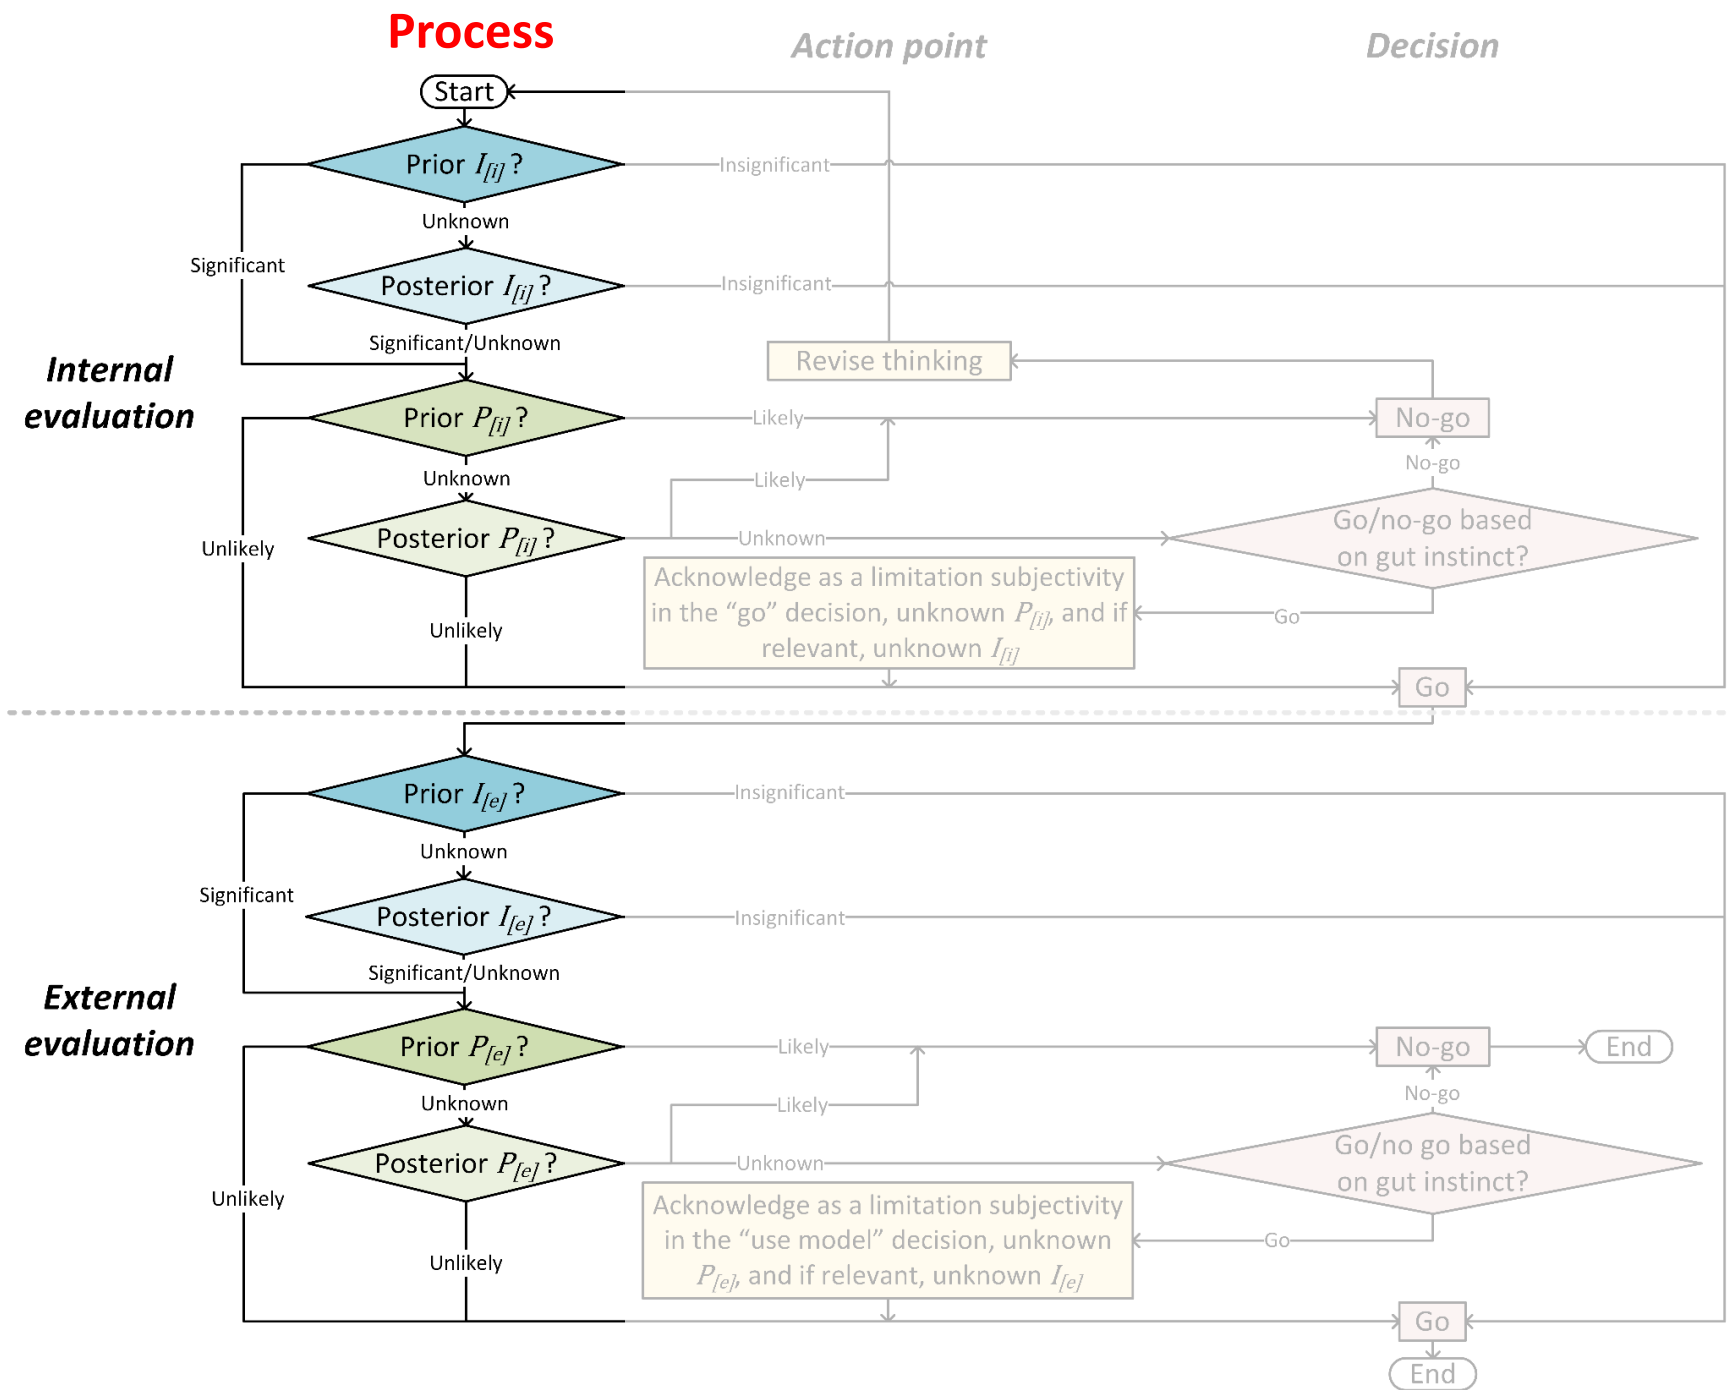

- To propose a framework for evaluating assumptions inherent to a top-down or bottom-up pharmacometric model

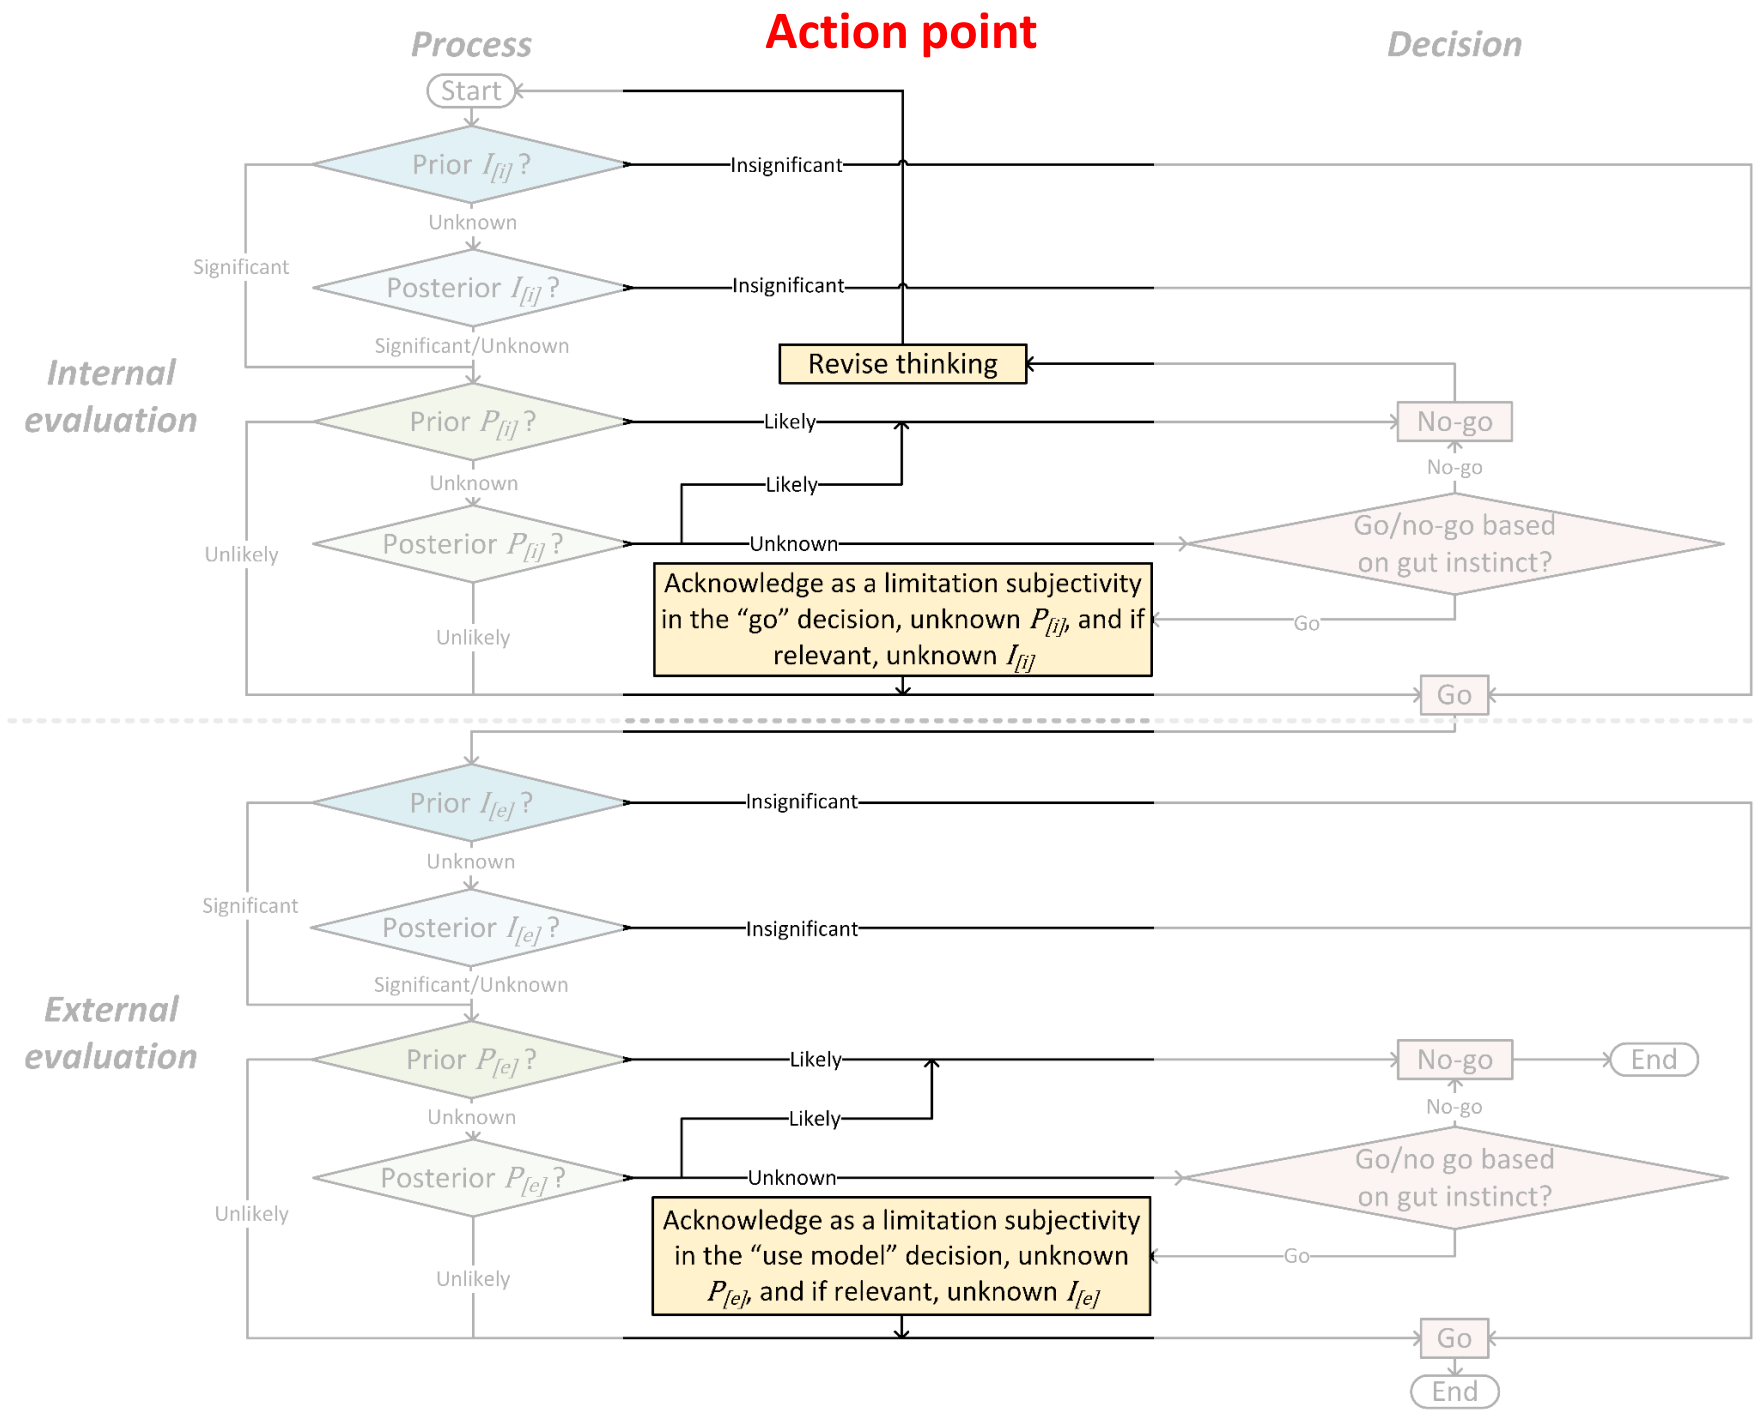

Classification of assumptions

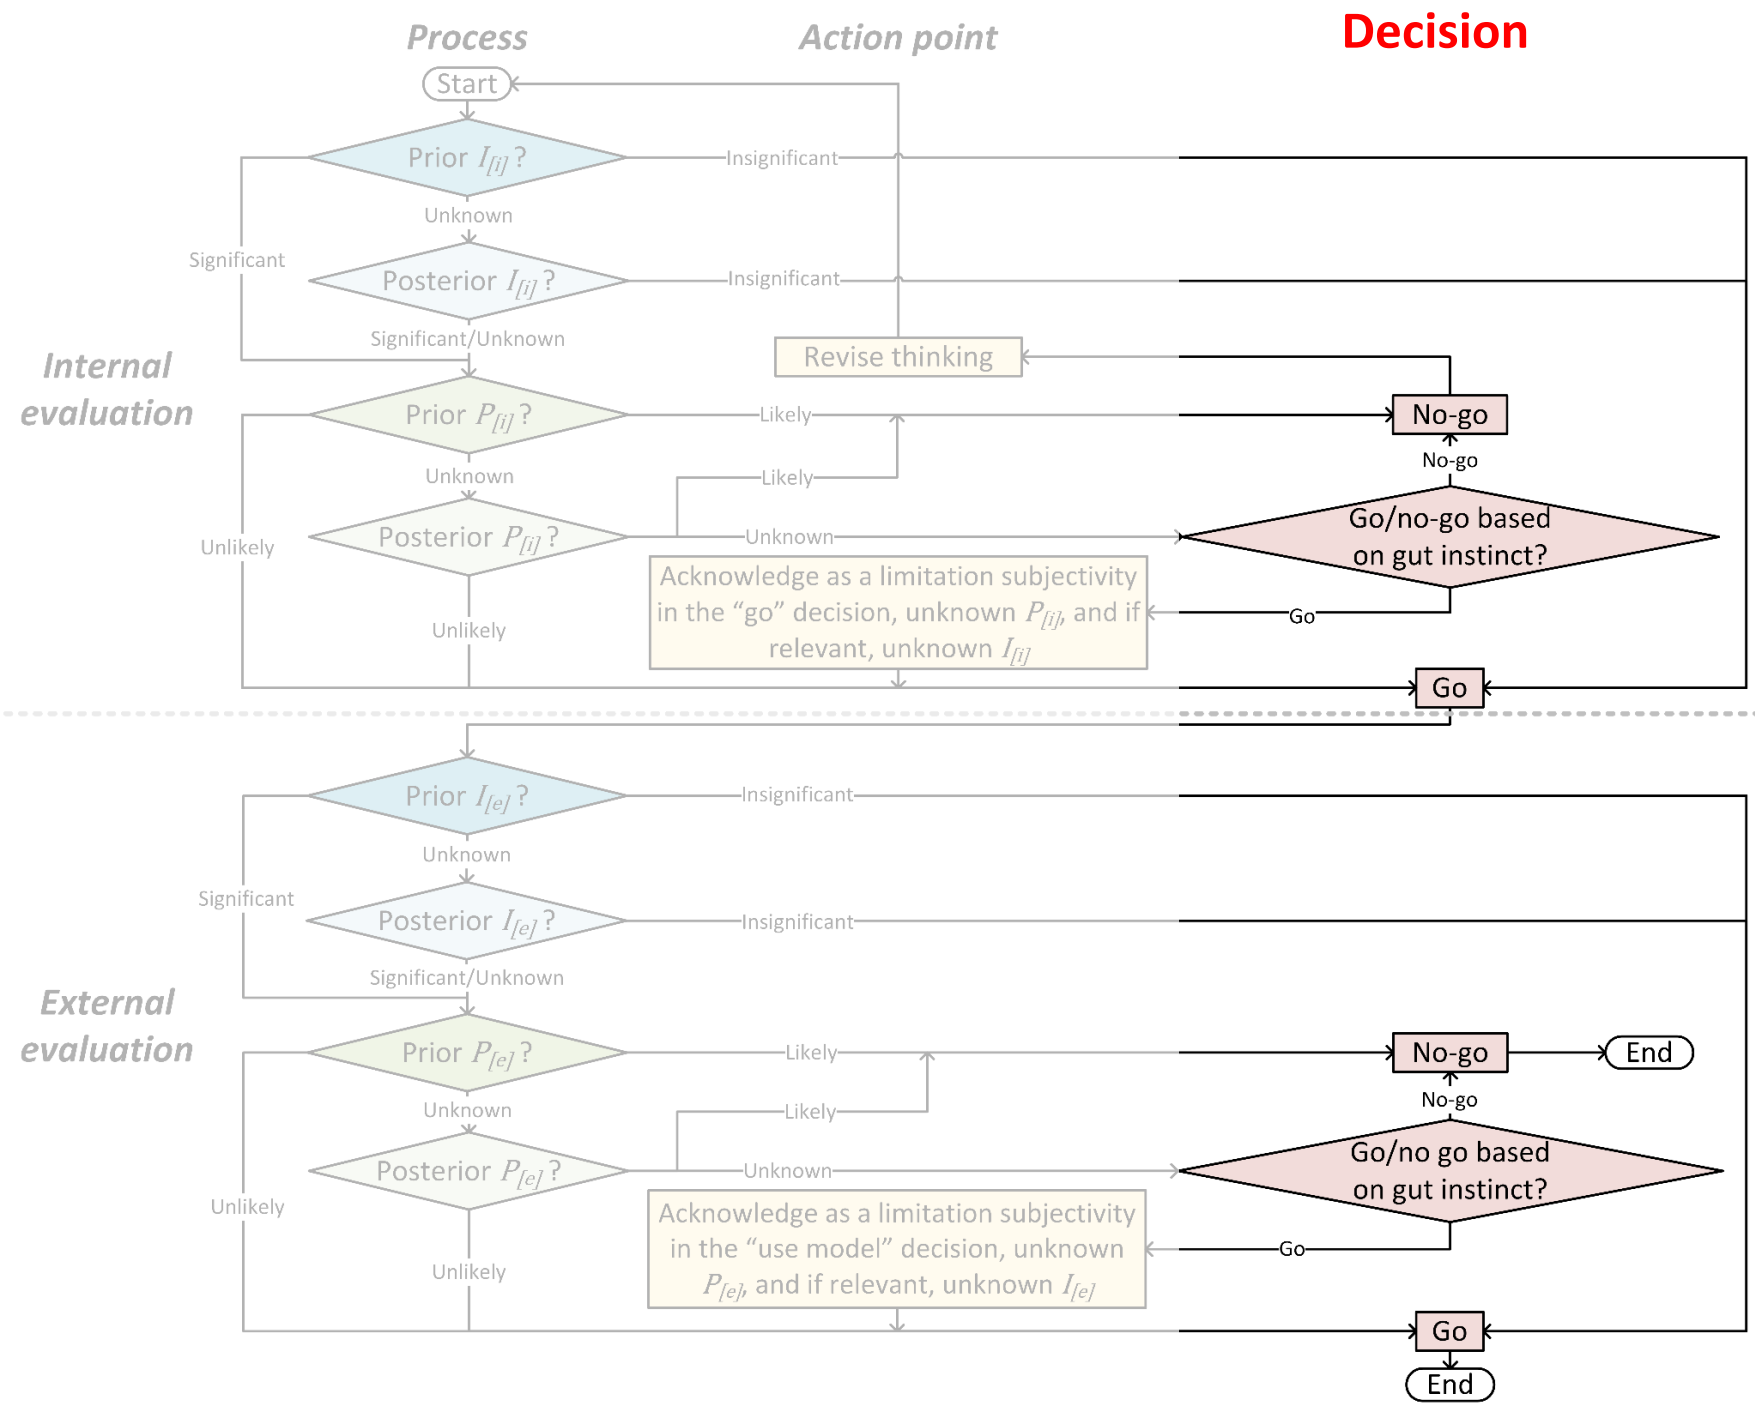

- Identification of assumptions → according to the **origin** of the assumption
- Implicit:
 - Arise from an **inherent component** of a method or model
 - e.g. Cockcroft-Gault equation implicitly assumes serum creatinine is at steady-state
 - e.g. Maximum likelihood method typically requires the observations to be iid
- Explicit:
 - Arise from the **application** of a method or model
 - e.g. Cockcroft-Gault equation provides an unbiased estimate of mGFR
 - e.g. The recorded blood sampling times are accurate

Flowchart for systematic evaluation of assumptions

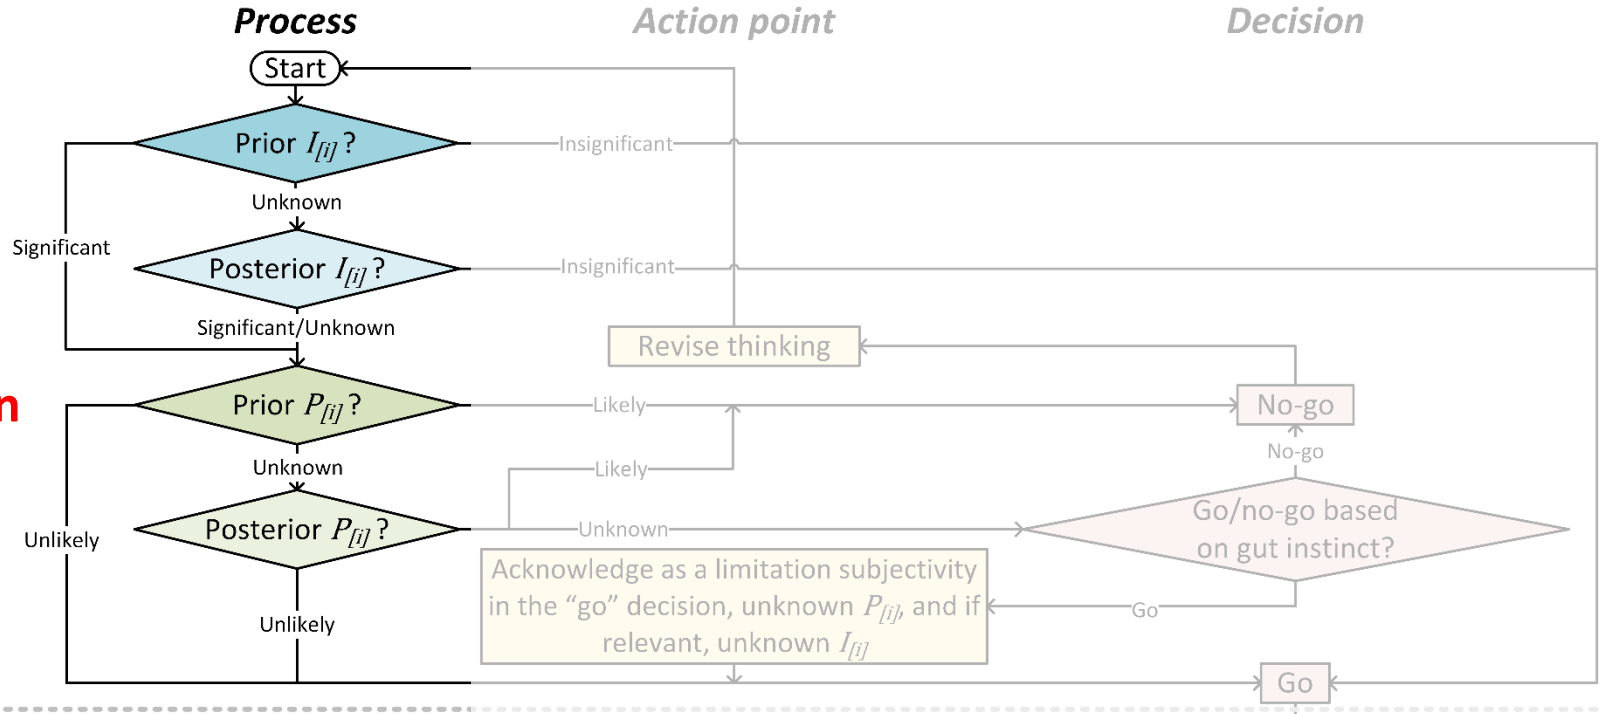

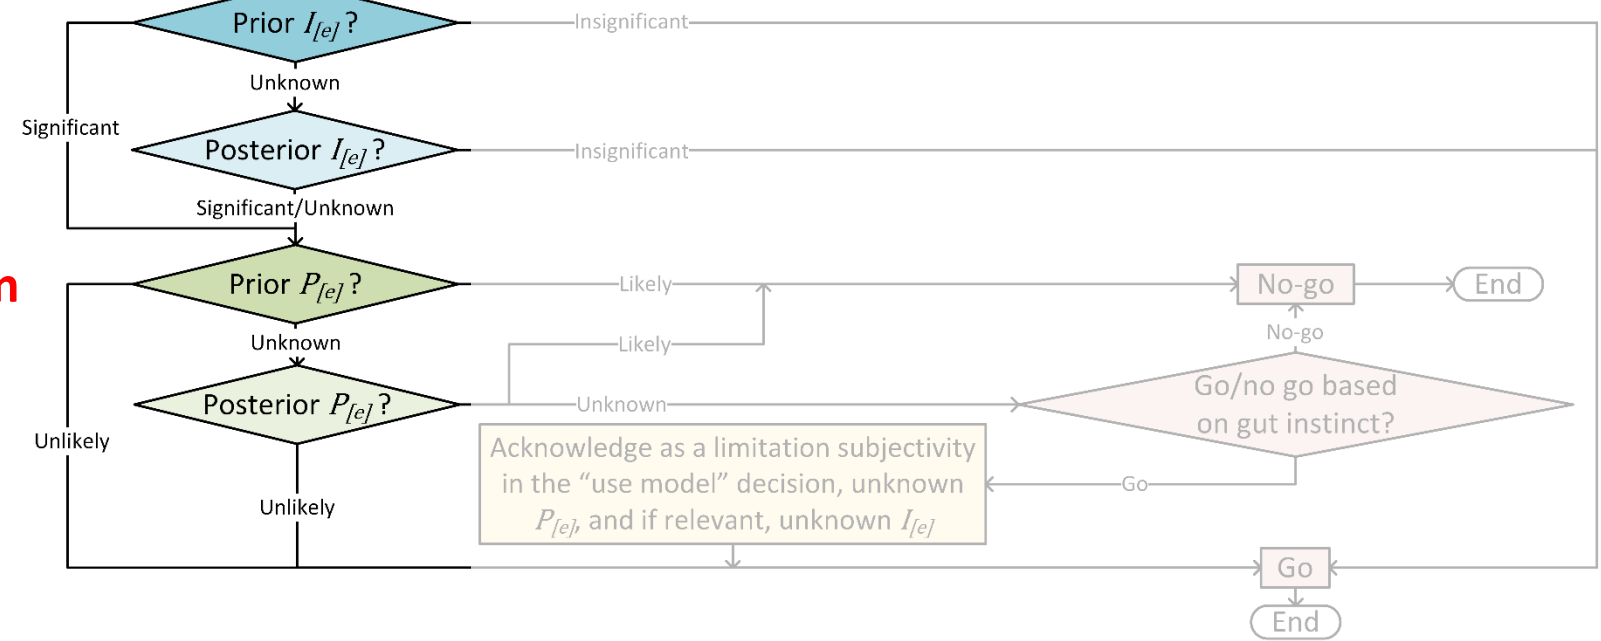

Internal evaluation

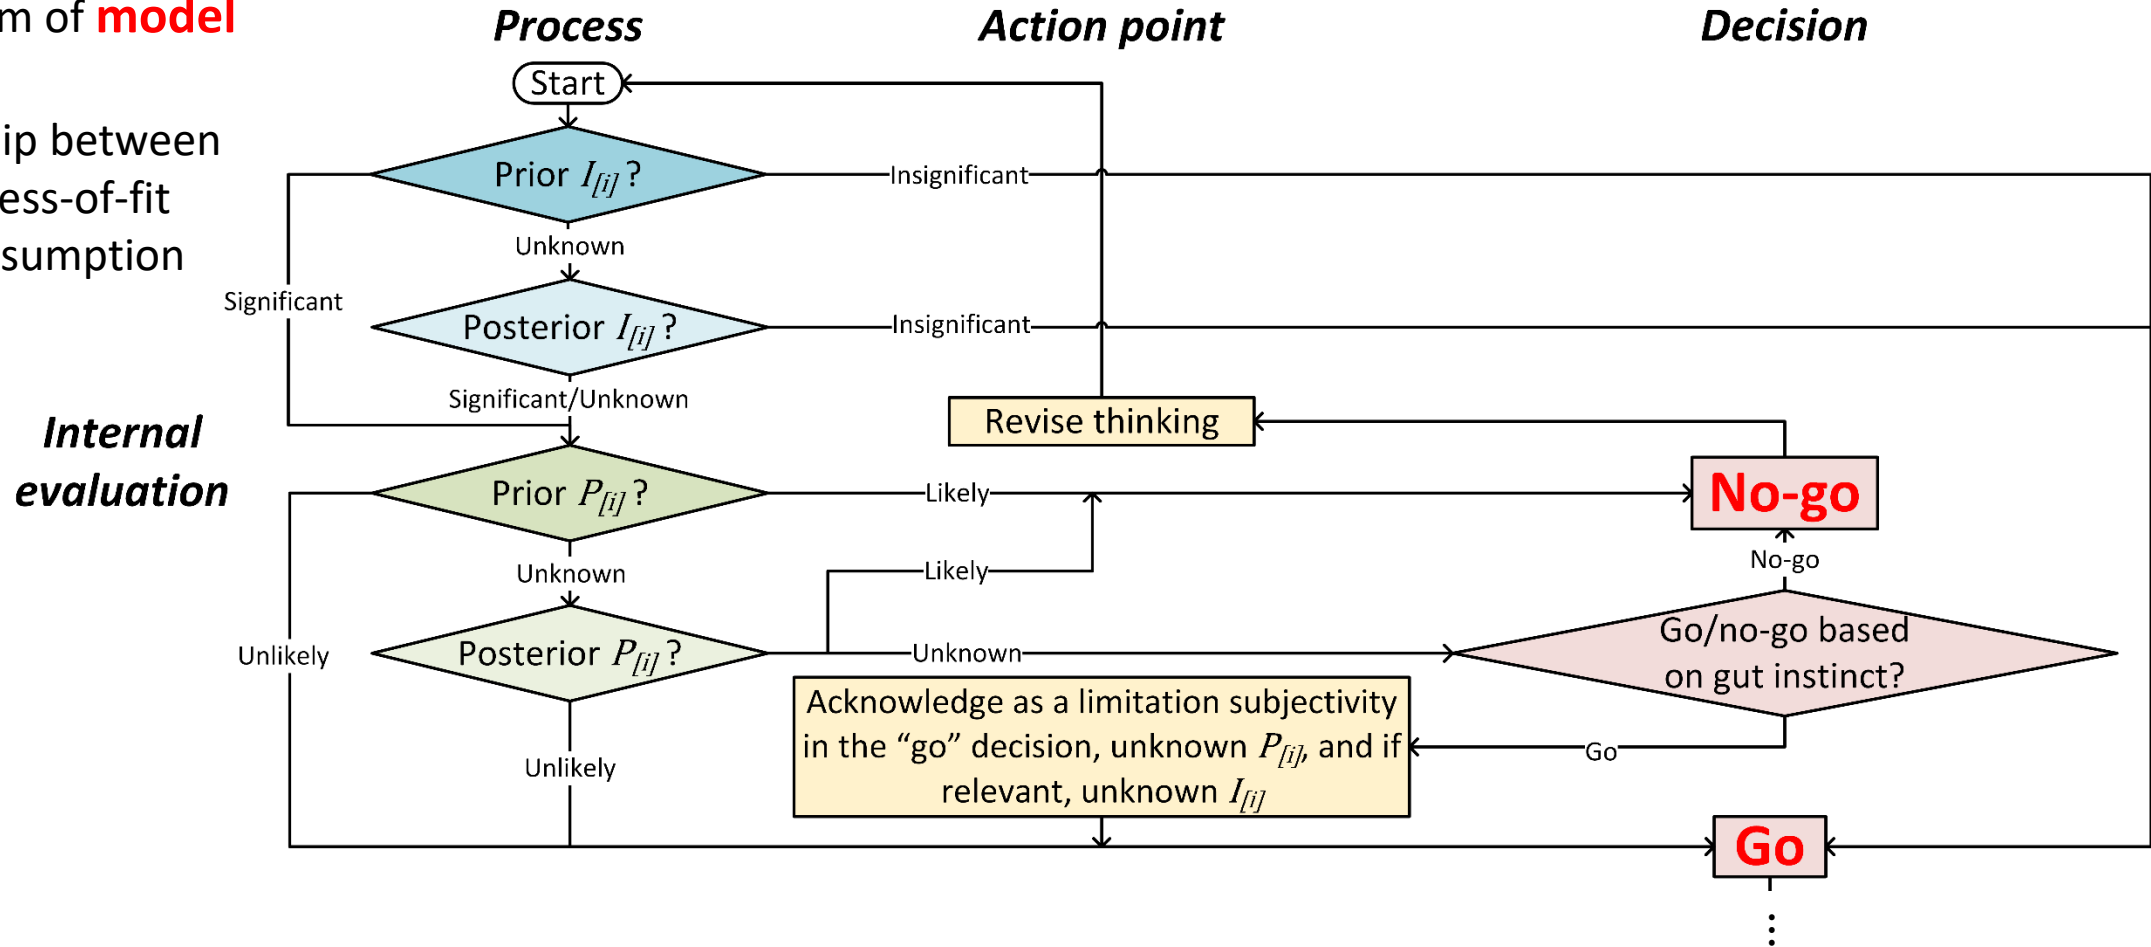

External evaluation

Internal evaluation

Internal evaluation:

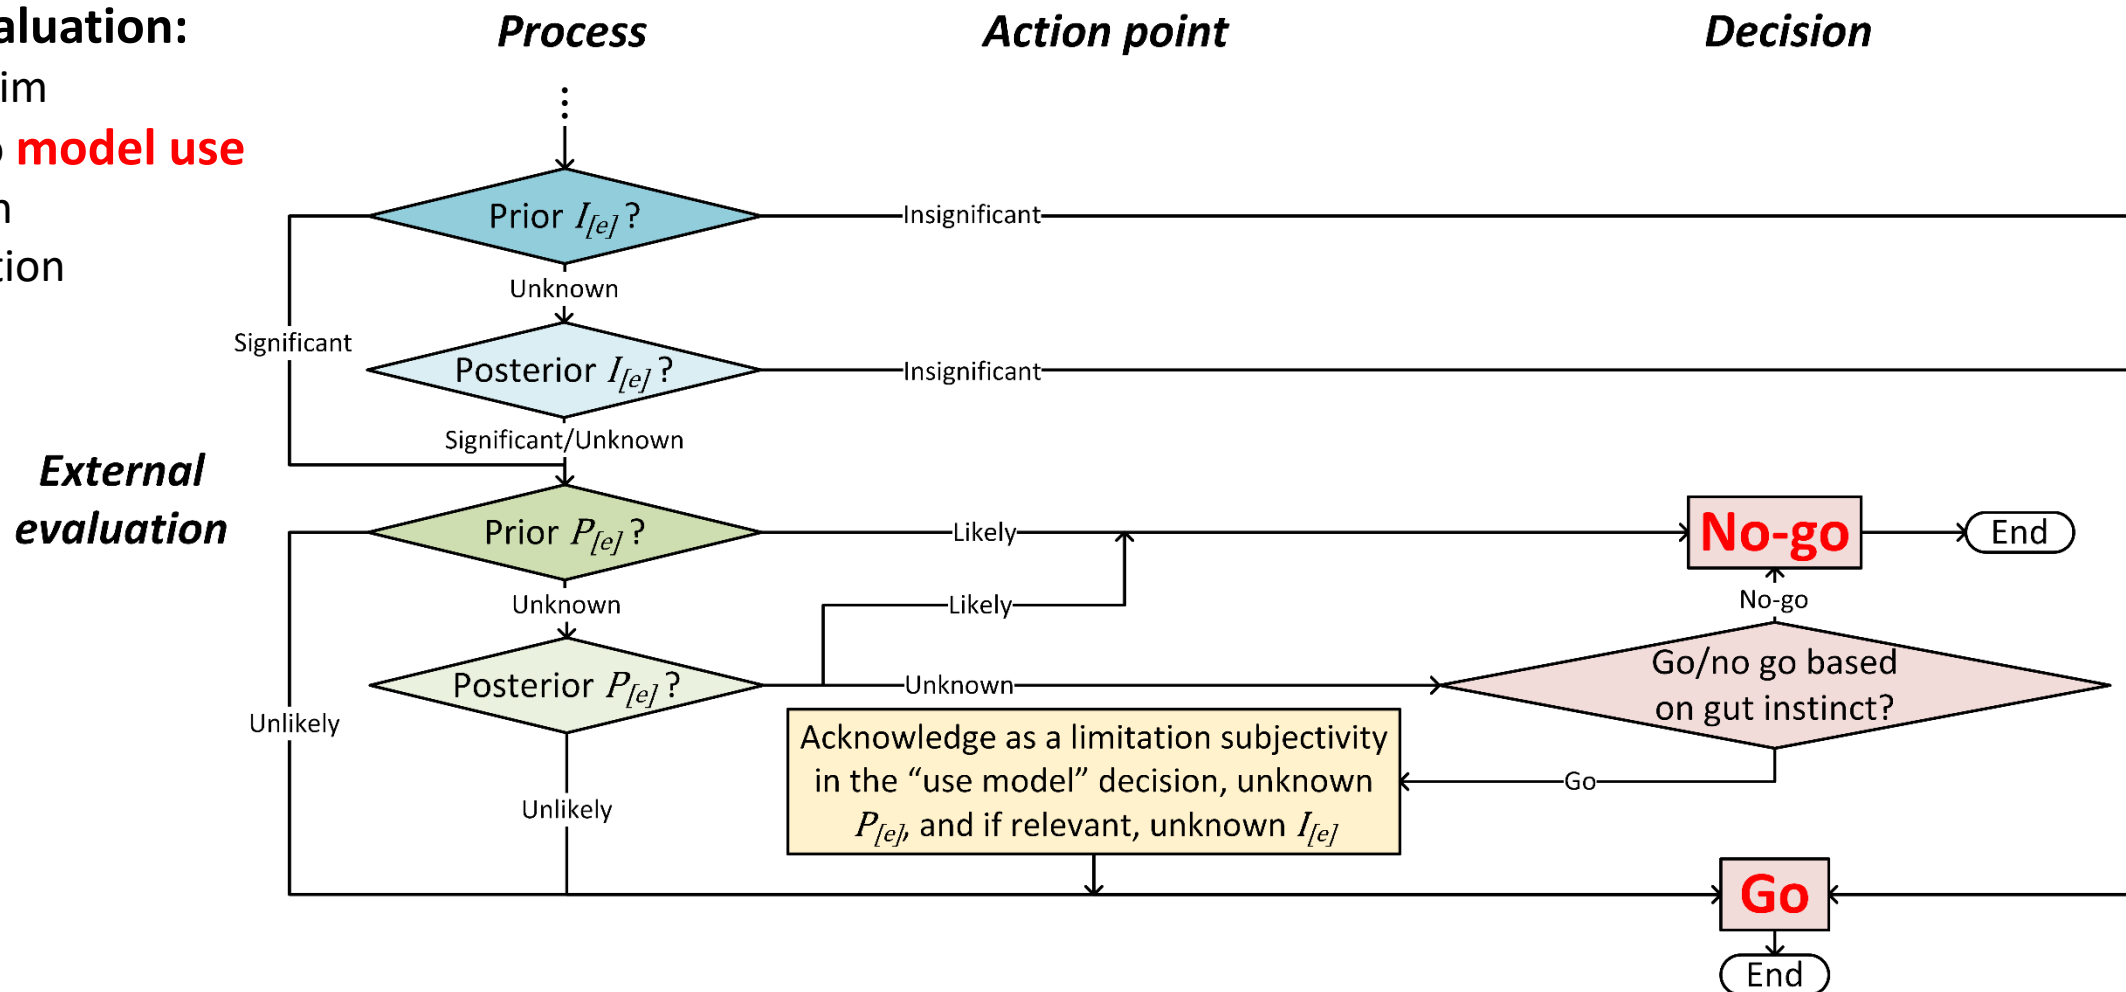

- Internal aim of **model building**
- Relationship between the goodness-of-fit and the assumption

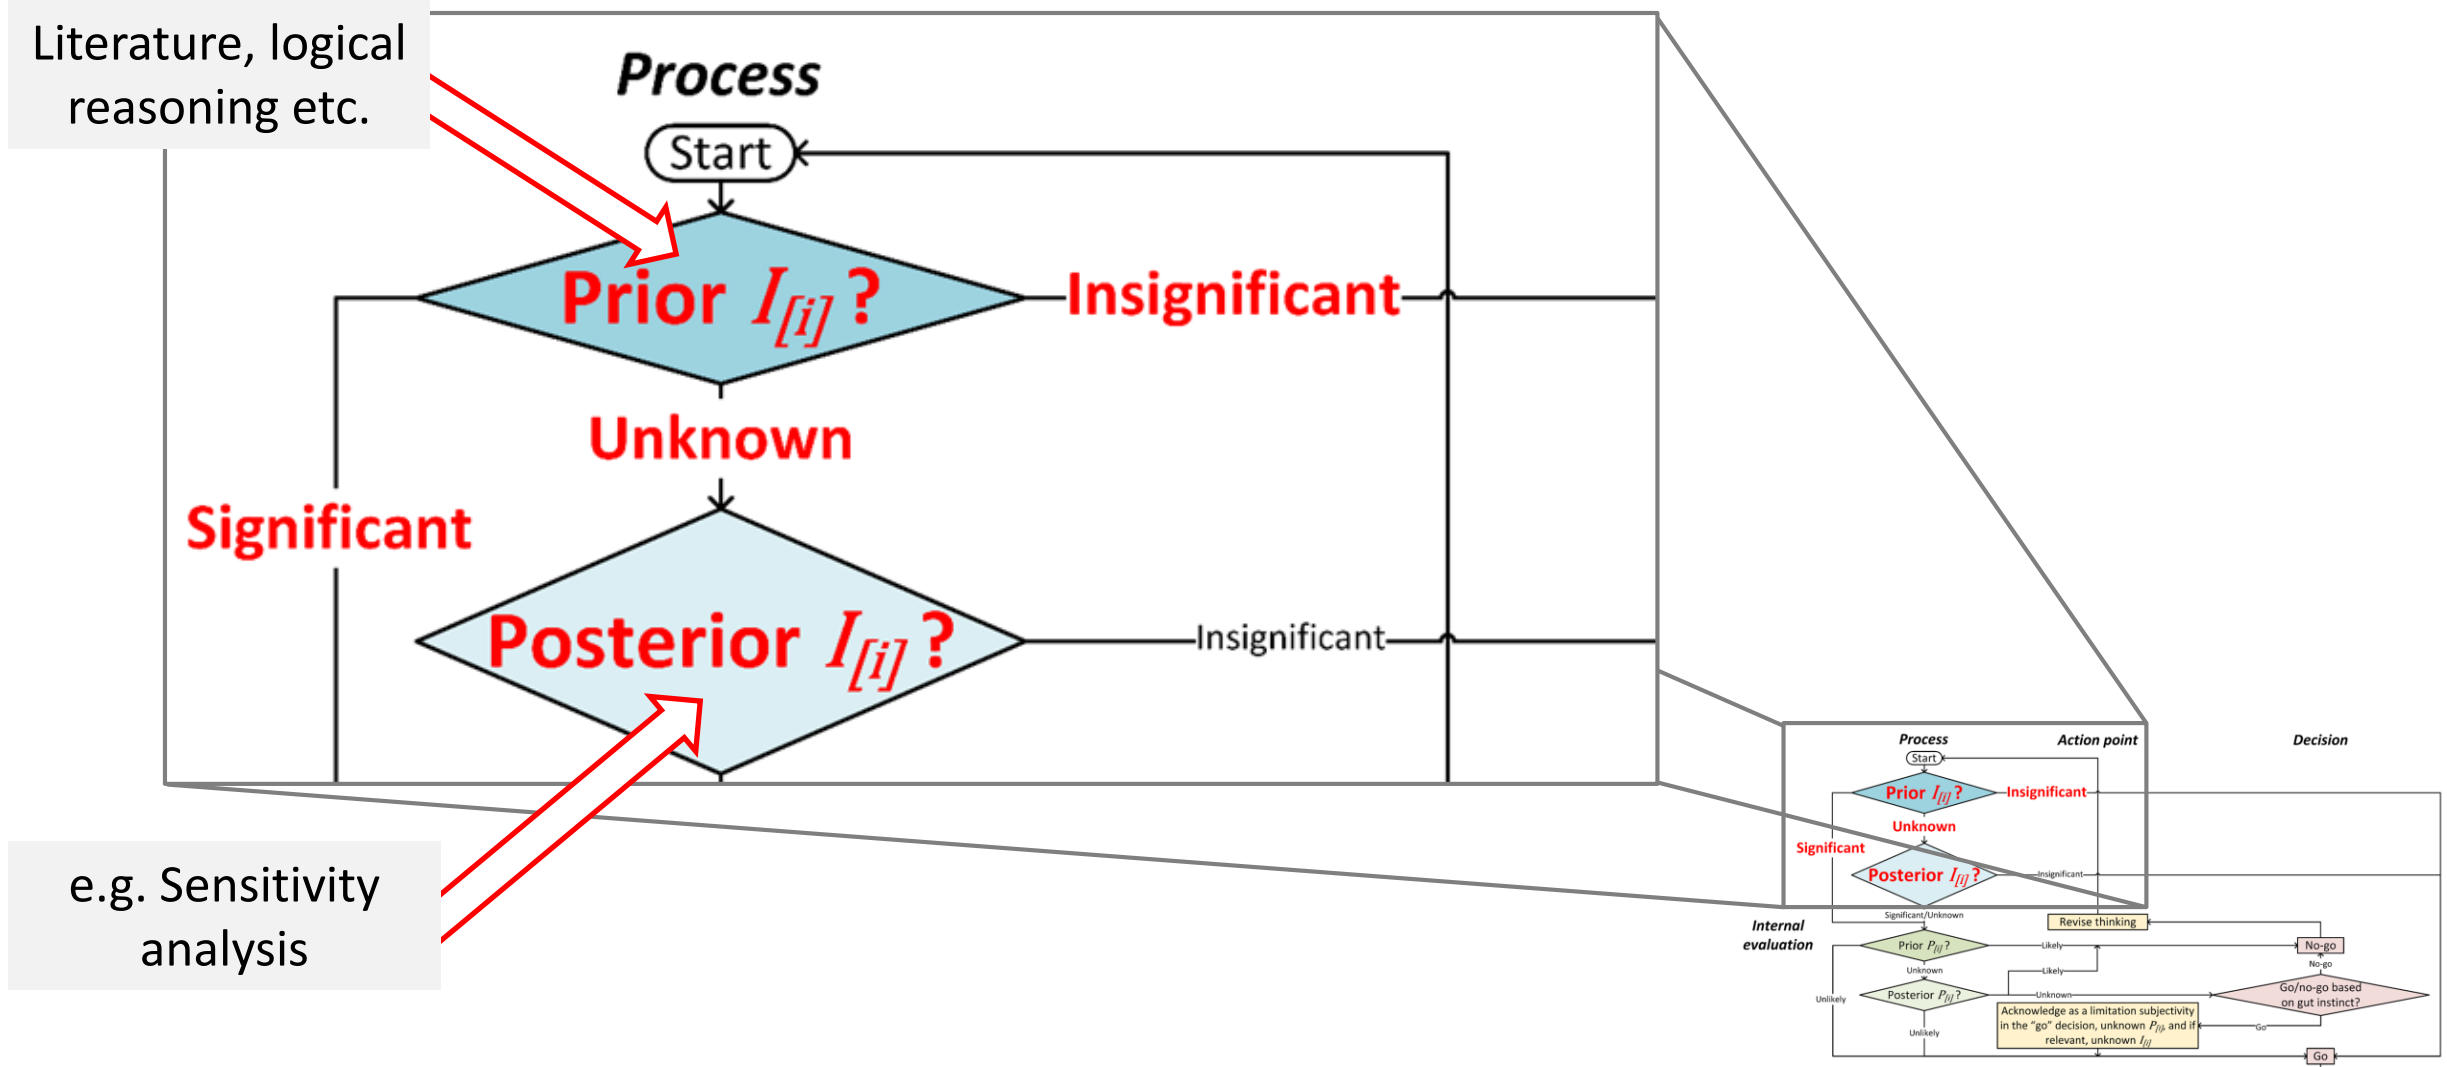

External evaluation

External evaluation:

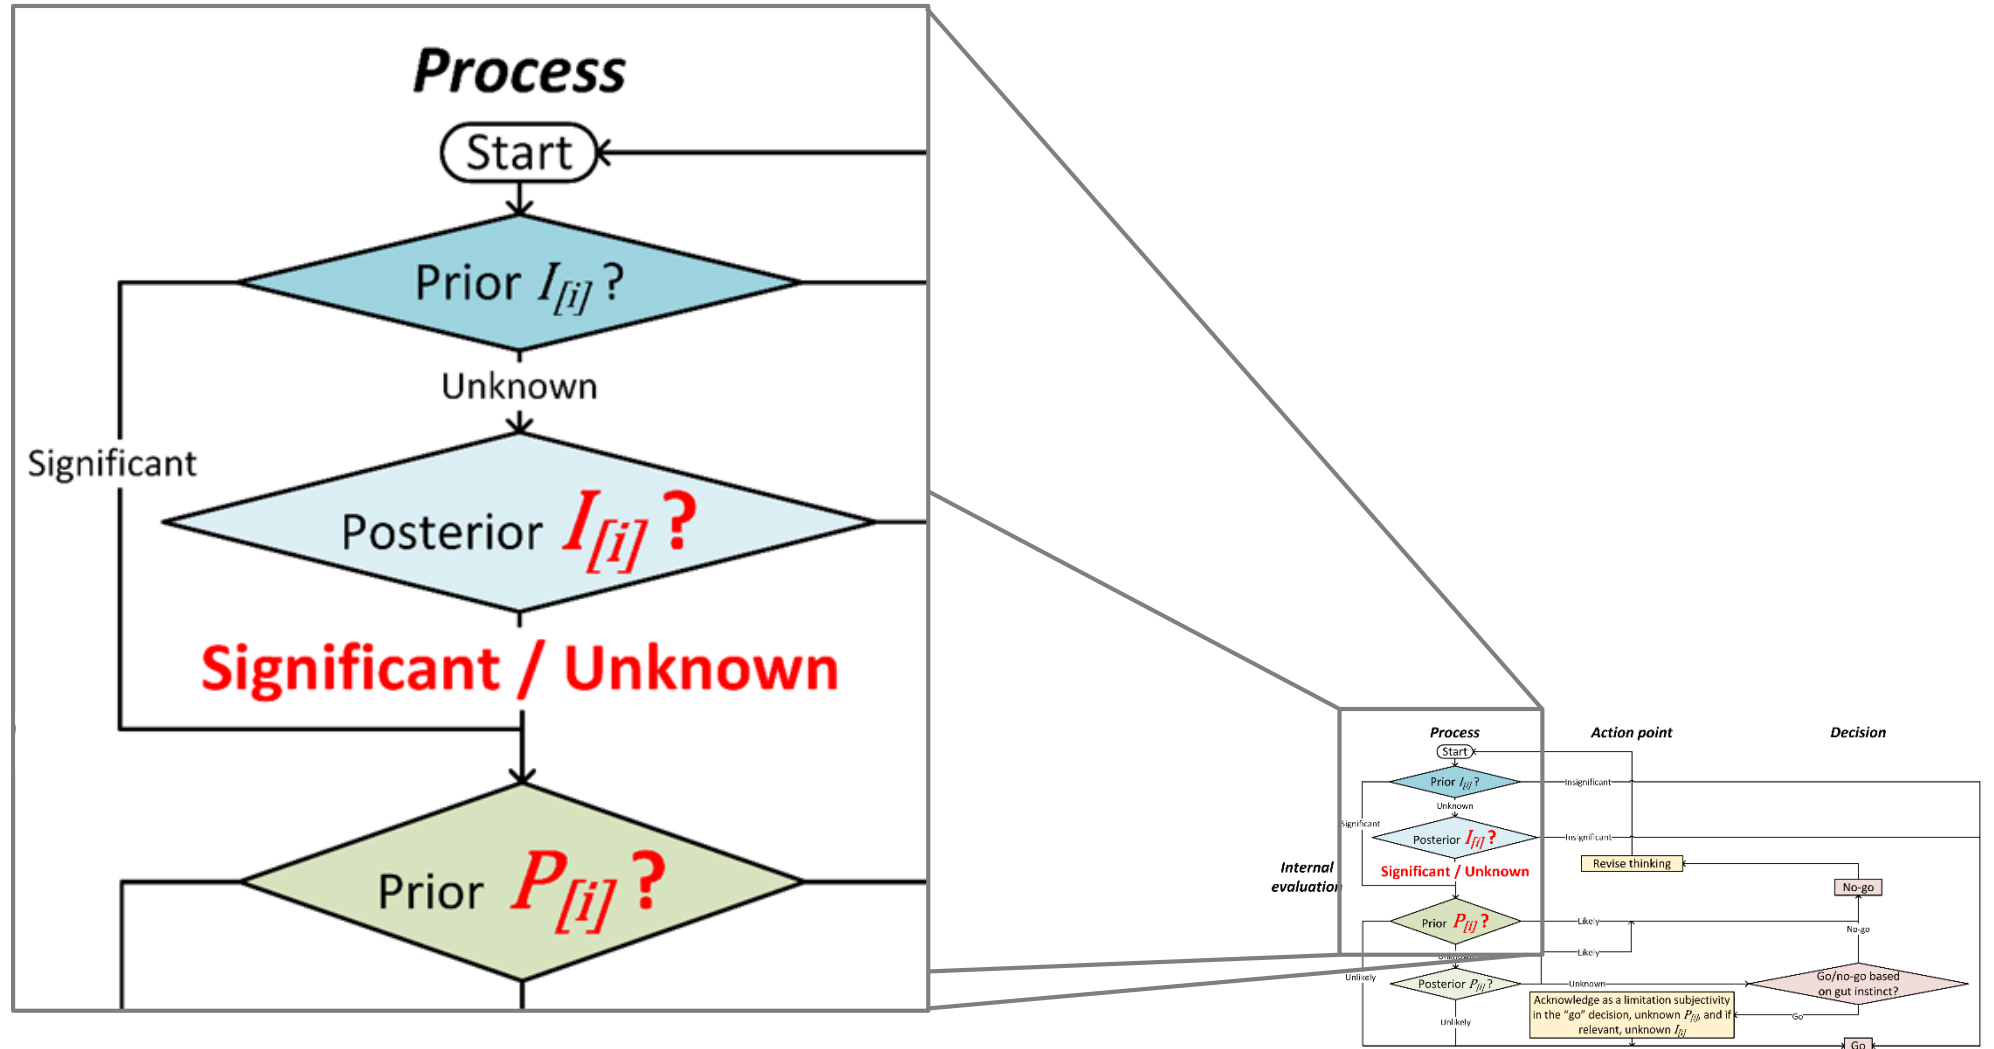

- External aim
- Related to **model use**
- Simulation
- Extrapolation

Impact of assumption violation, I

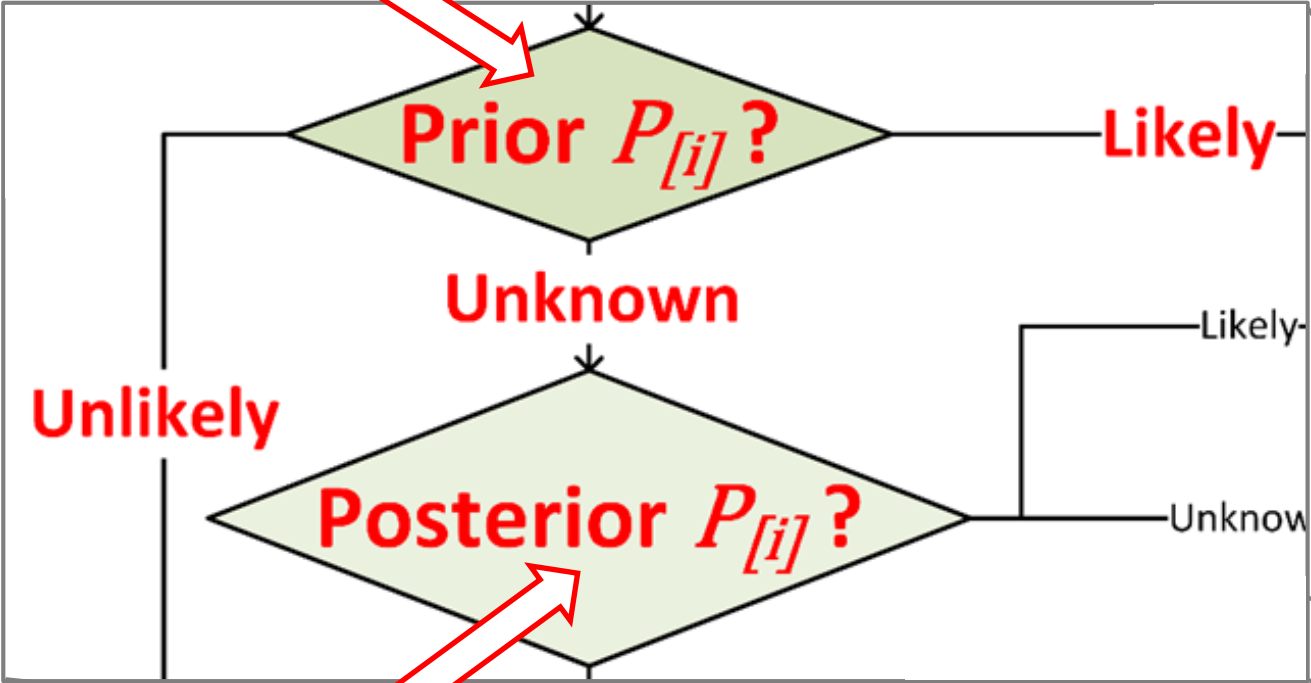

Risk stratification based on I

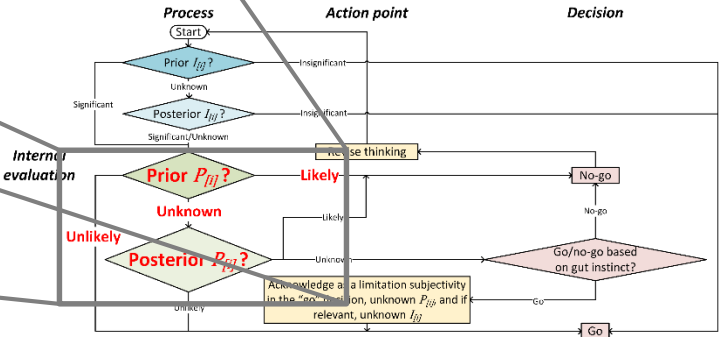

Probability of assumption violation, P

Literature, logical reasoning etc.

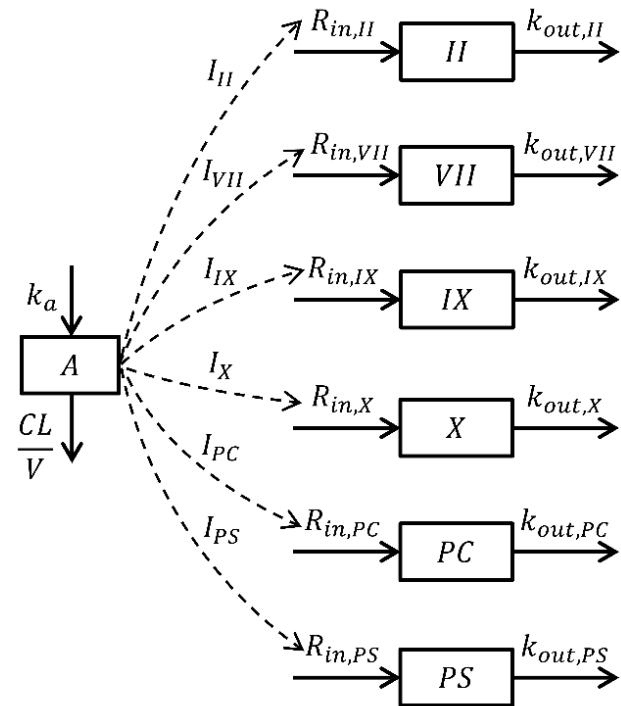

Modelling, simulations etc.

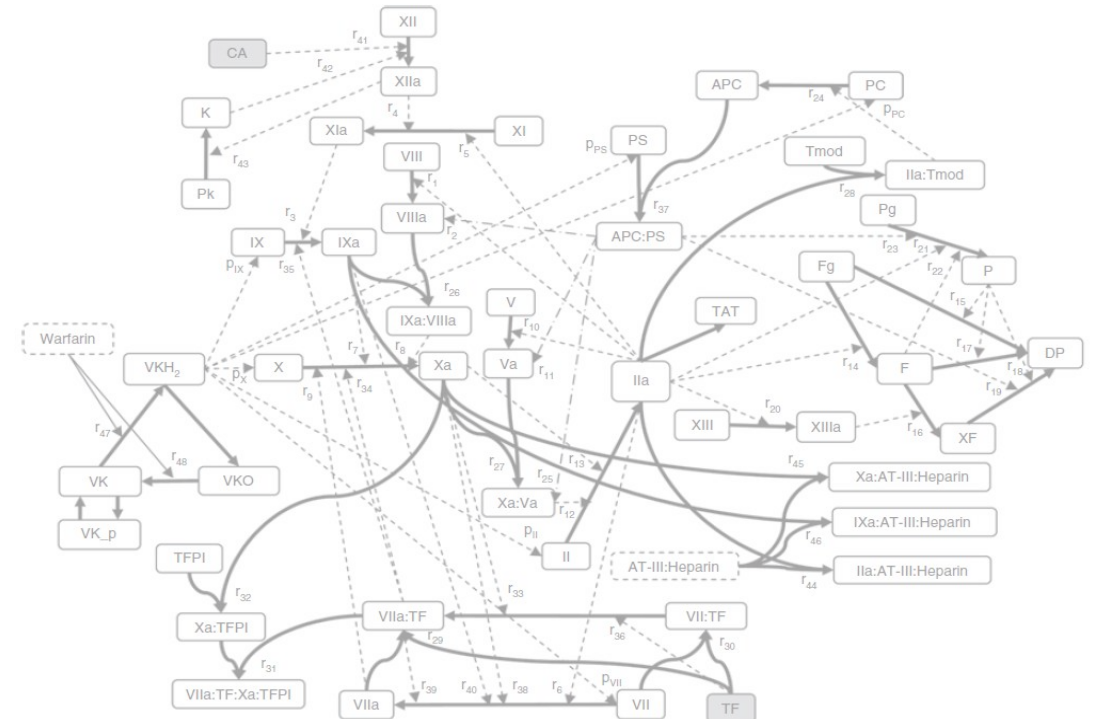

Application

- Top-down example
 - To develop a K-PD model for warfarin and vitamin K-dependent coagulation proteins

Ooi et al., Clin Pharmacokinet. 2017; 56(12):1555-66

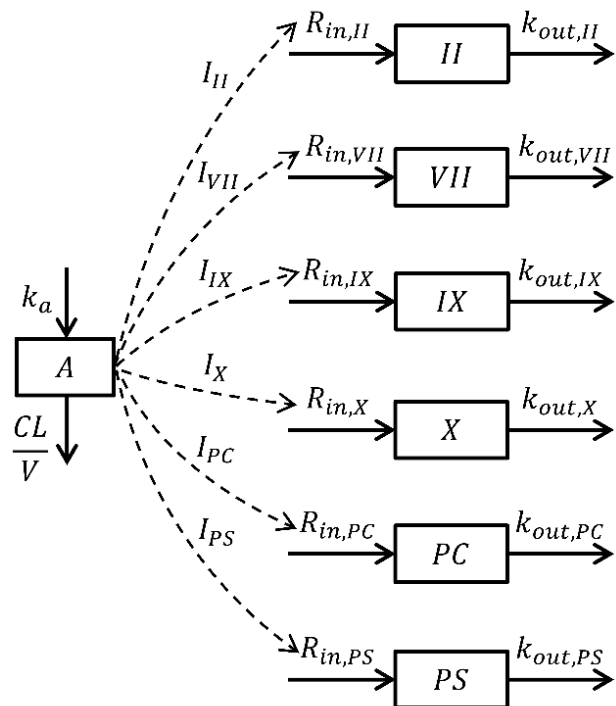

- Bottom-up example
 - Factor VII-based method for INR prediction based on a QSP coagulation network model

Wajima et al., Clin Pharmacol Ther. 2009;86(3):290-8

Demonstration of the utility of the flowchart

- Top-down example
 - To develop a K-PD model for warfarin and vitamin K-dependent coagulation proteins

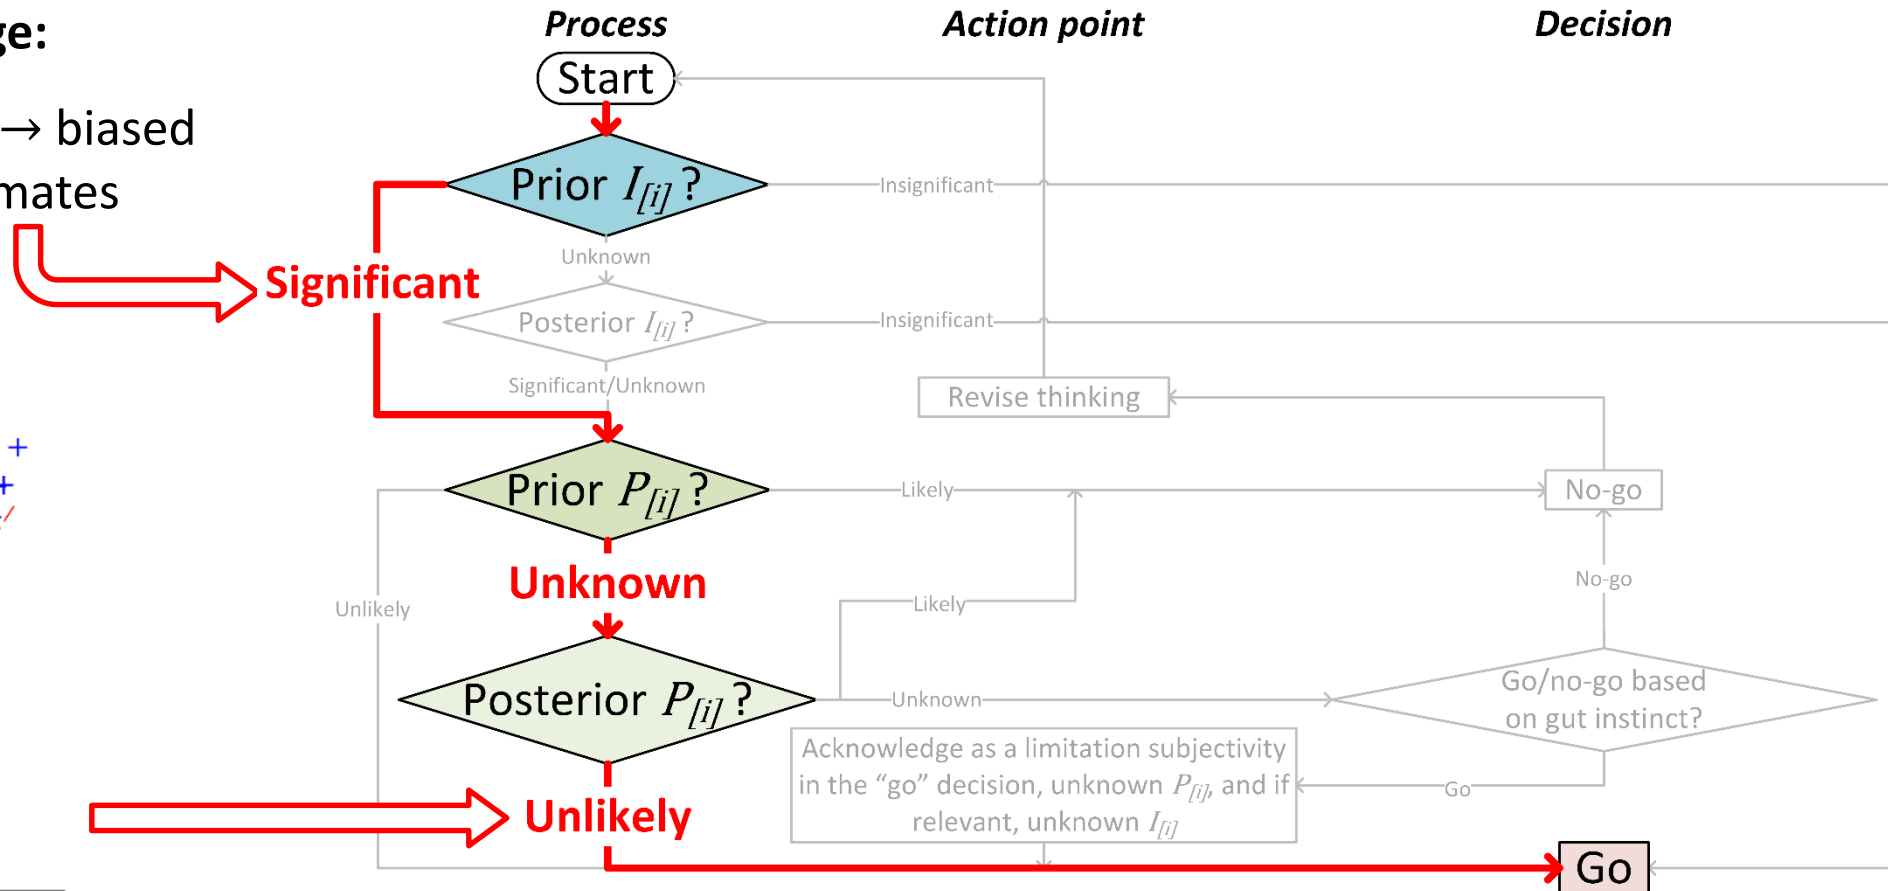

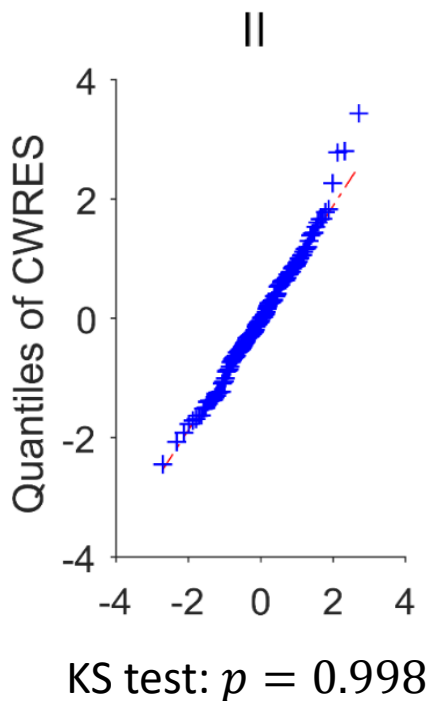

1. **Internal** evaluation of **implicit** assumption
2. **Internal** evaluation of **explicit** assumption
3. **External** evaluation of **implicit** assumption
4. **External** evaluation of **explicit** assumption

1. Internal evaluation of implicit assumption: $\varepsilon \sim N(0, \sigma^2)$

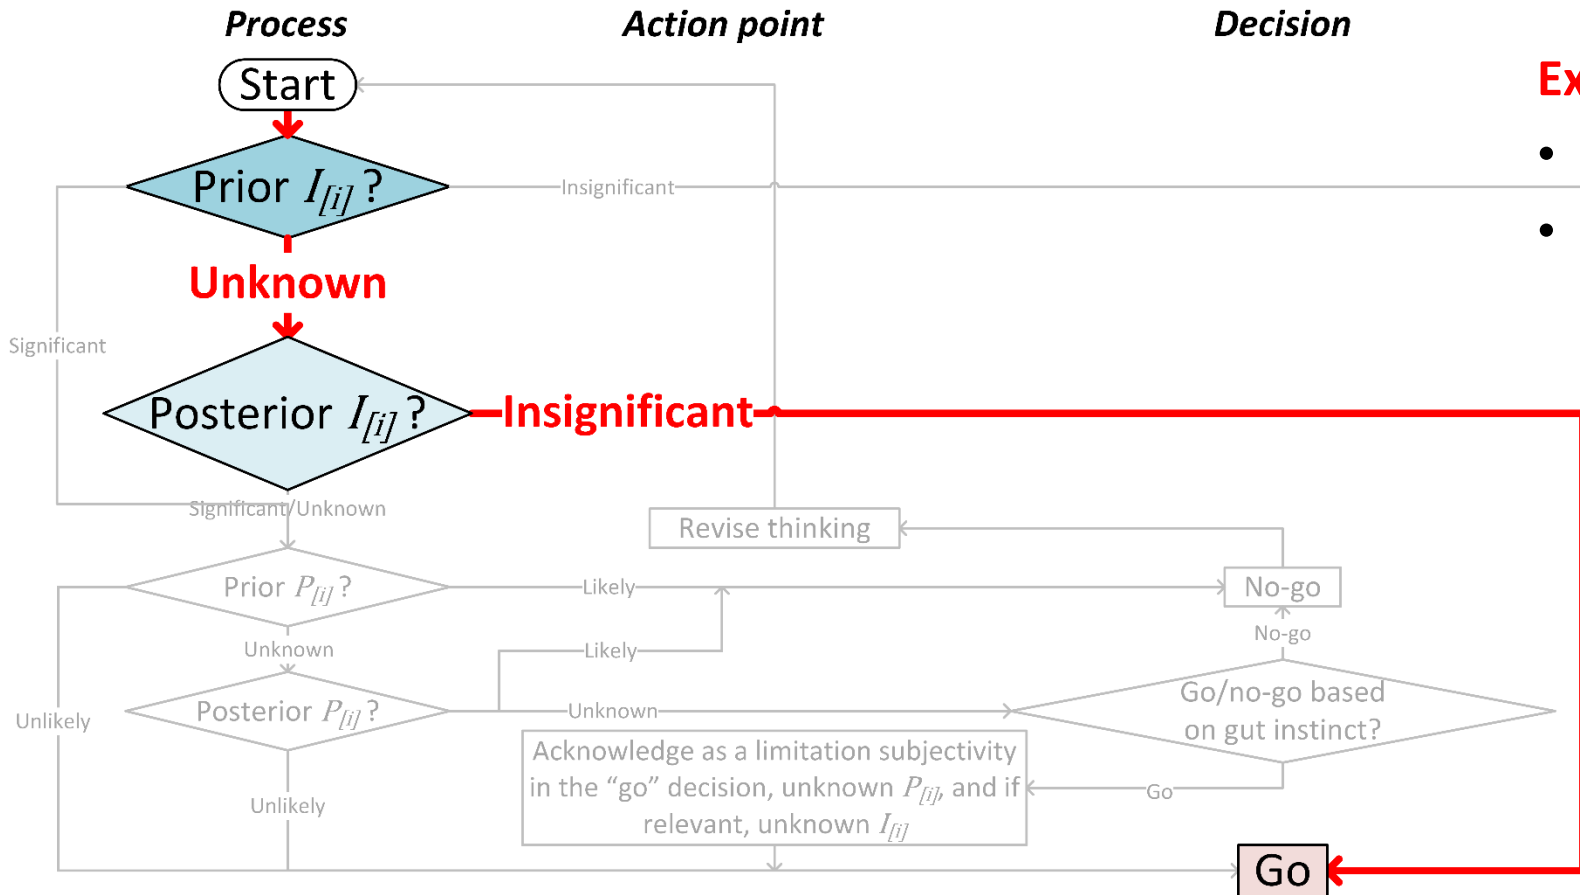

Prior knowledge:

Non-normality → biased parameter estimates

$I_{[i]} = \text{Significant}, P_{[i]} = \text{Unlikely}$
 Decision = **Go (model building)**

2. Internal evaluation of explicit assumption: Daily dose time of 6pm

Explicit assumption:

- Actual daily dose time not recorded
- Based on study protocol → **imputation**

Sensitivity analysis

Imputed daily dose time	OFV
8 a.m.	5298
8 p.m.	5298

$I_{[i]}$ = Insignificant

Decision = **Go (model building)**

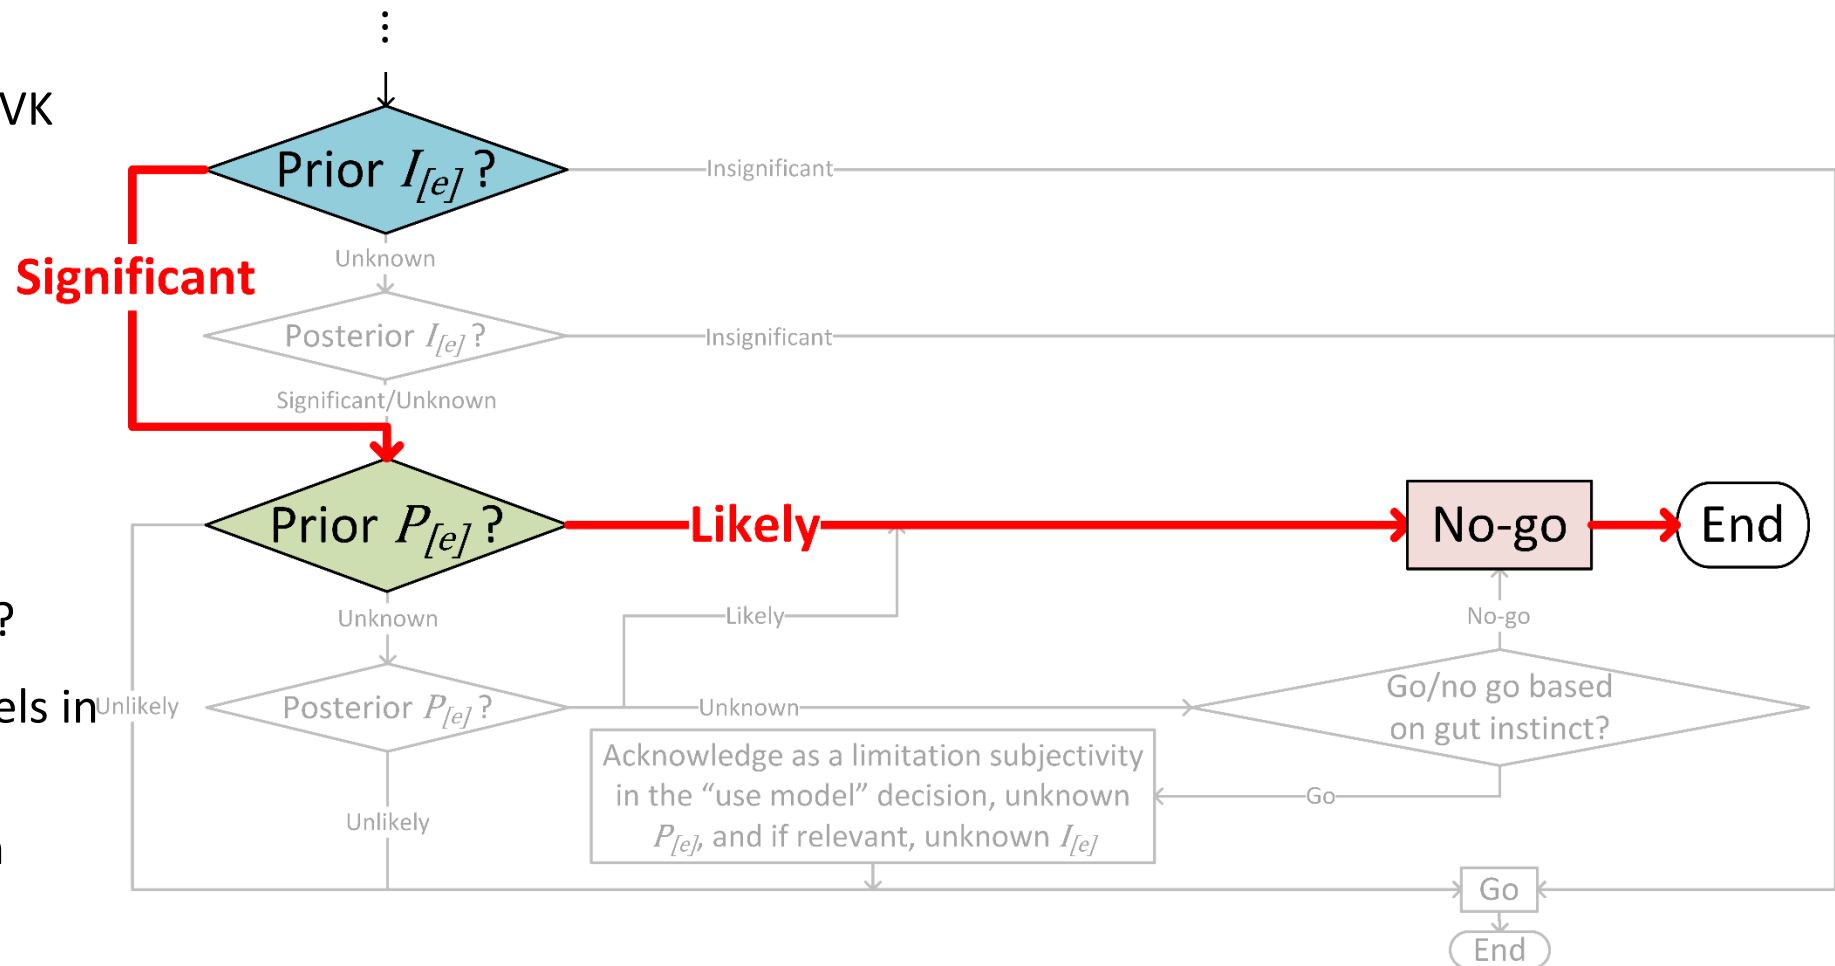

3. External evaluation of implicit assumption: Reversible binding

E_{max} model:

- Binding of warfarin and VK to VKOR \rightarrow reversible
- Constant VK

External evaluation:

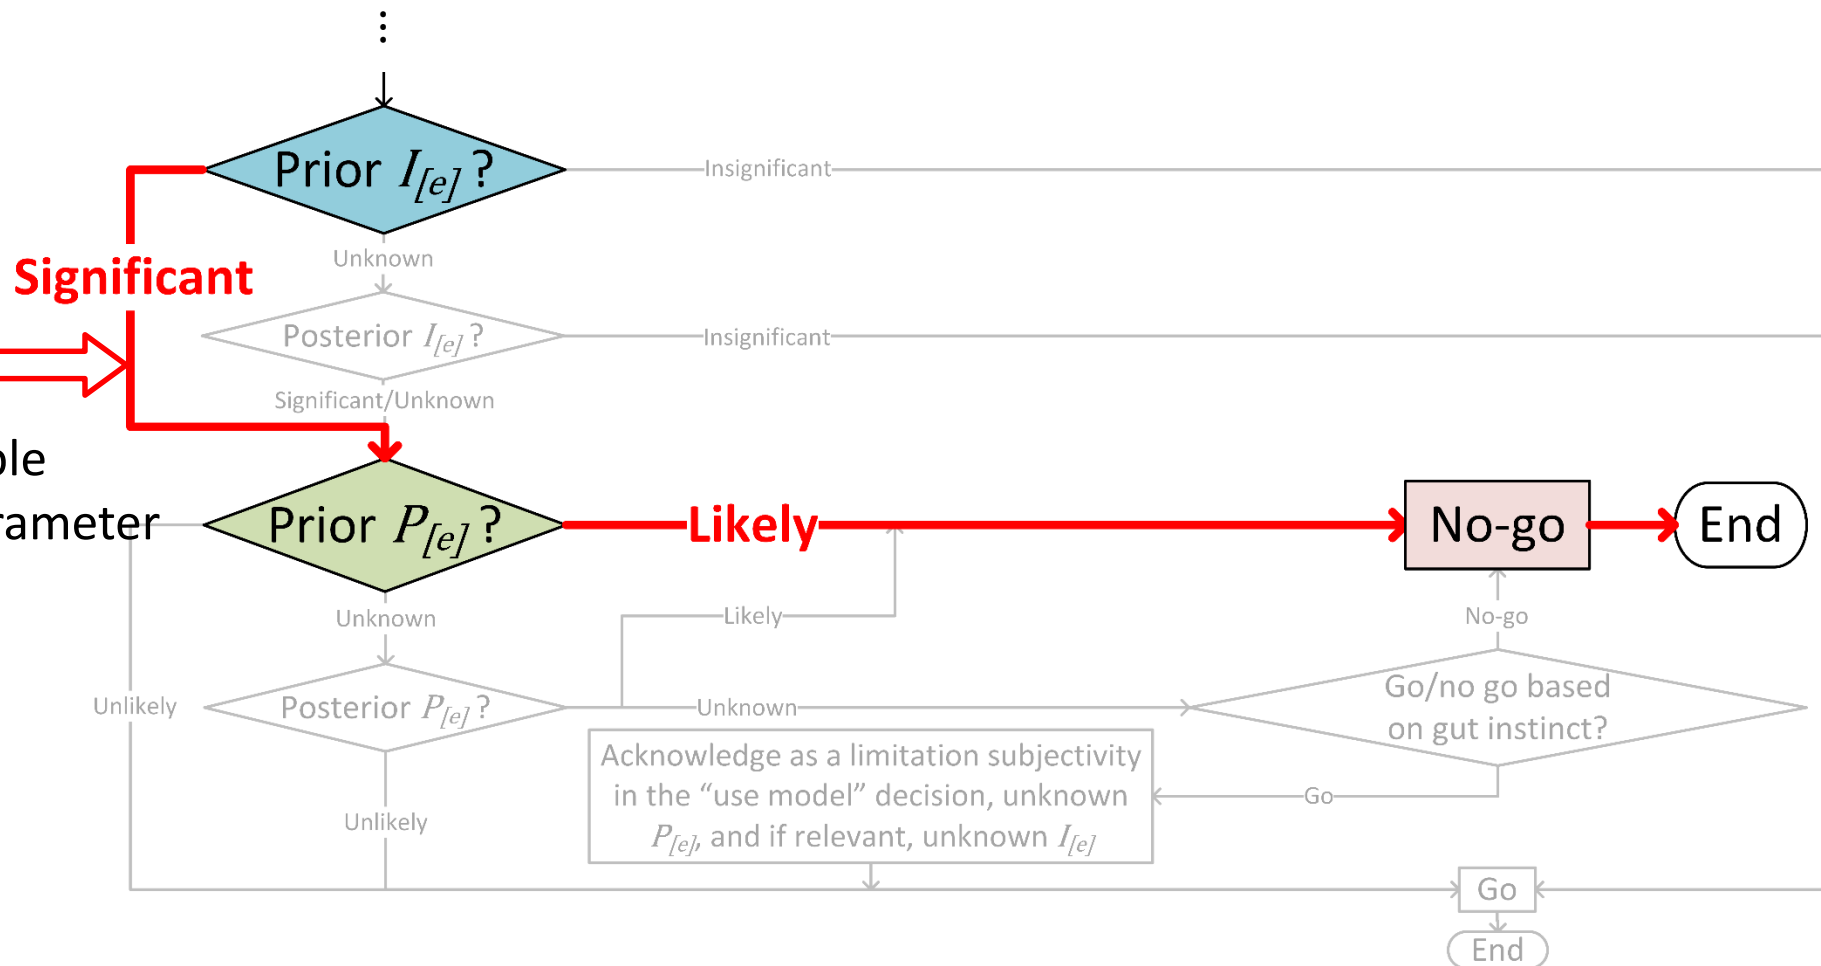

- How to evaluate an assumption against an **external aim** of interest?
- To predict the factor levels in **different population**
e.g. VK supplementation

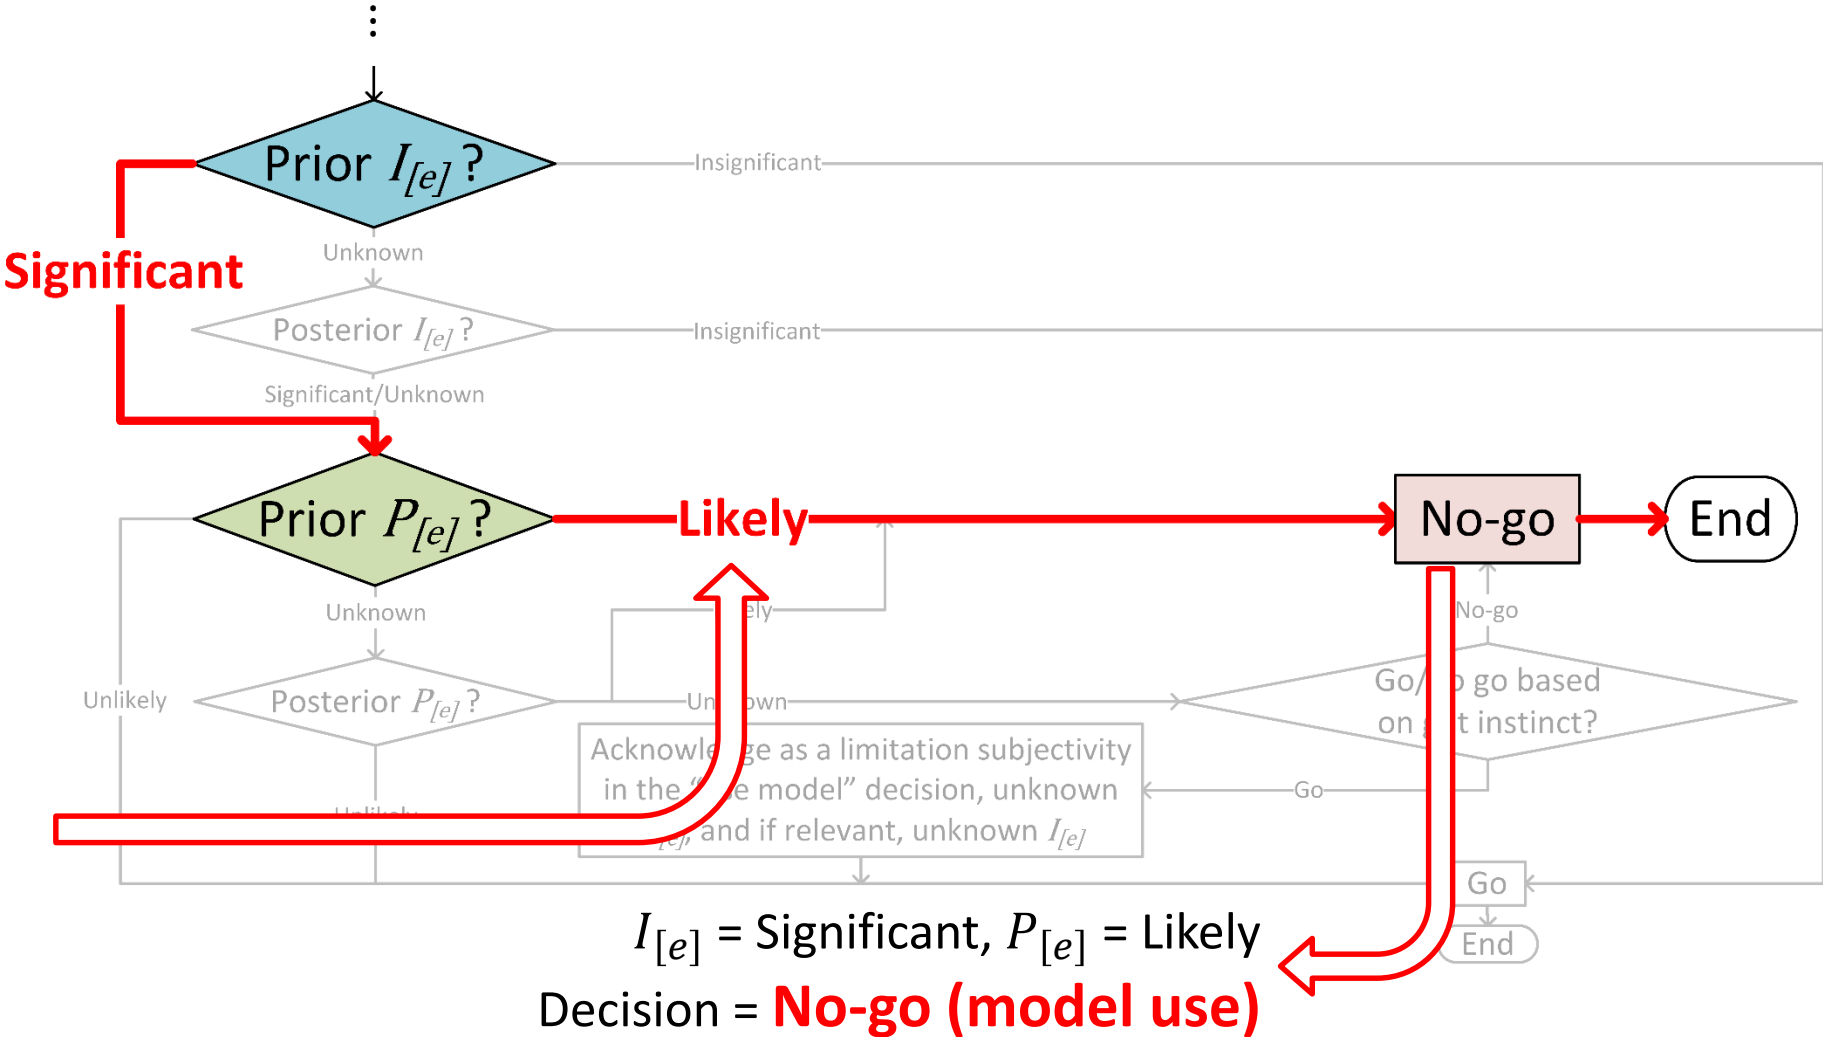

3. External evaluation of implicit assumption: Reversible binding

Sensitivity analysis:

- Deviation from reversible binding or different parameter estimates (e.g. A_{50})
- Different predictions

3. External evaluation of implicit assumption: Reversible binding

Prior knowledge:

- VK supplementation
- Variable A_{50} i.e. $A_{50}(t)$
- Extrapolation to new population → biased predictions

4. External evaluation of explicit assumption:

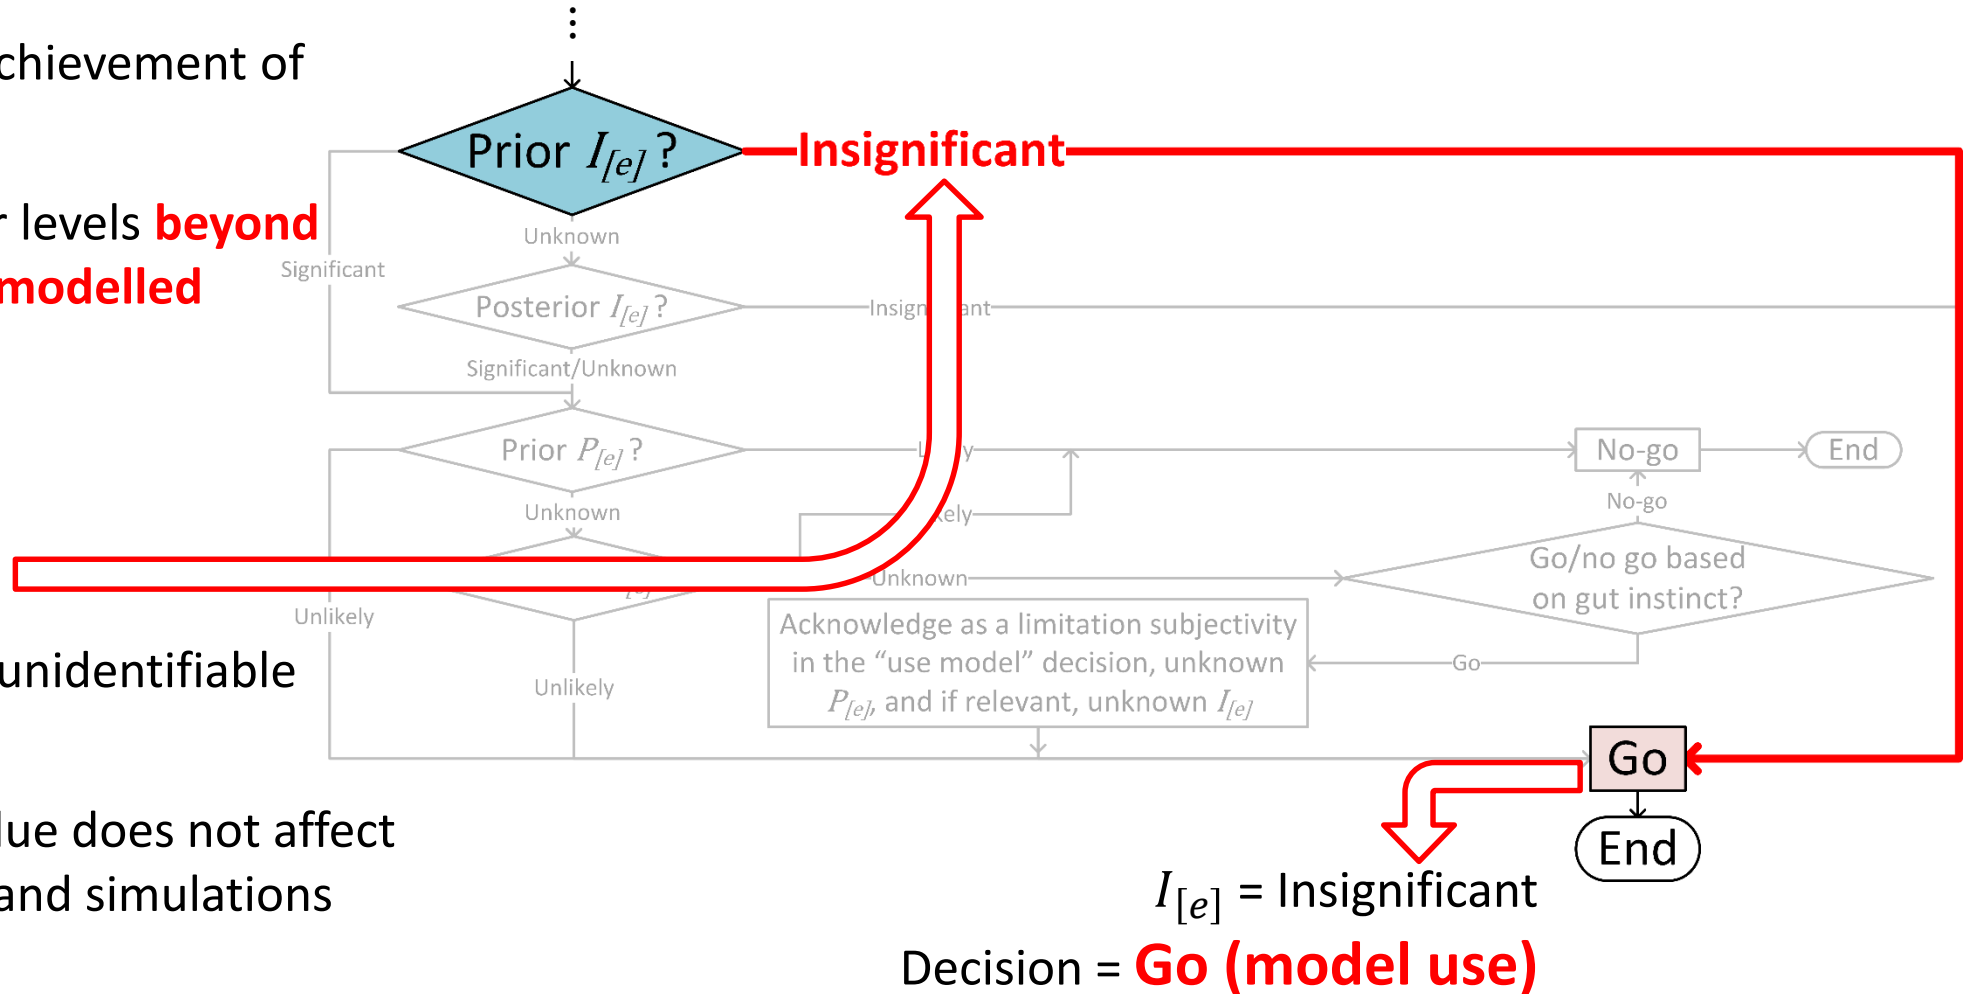

$$V = 8L$$

External evaluation:

- Impact on the achievement of **external aim**
- To predict factor levels **beyond the dose range modelled**

Prior knowledge:

- V is structurally unidentifiable without PK data
- The assumed value does not affect K-PD model fits and simulations

Suggested assumption table

- Documentation of assumptions → EFPIA's white paper on good practices in MID3
- Adapted and expanded for use in concert with the flowchart

Assumption	Impact (<i>I</i>)			Probability (<i>P</i>)			Decision
	Methods	Results	Rating	Methods	Results	Rating	
State the assumption	Prior or posterior? Testable? Outline method	Summarise results and justify rating	Significant / insignificant / unknown	Prior or posterior? Testable? Outline method	Summarise results and justify rating	Likely / unlikely / unknown	Go or no-go for model building or model use

EFPIA MID3 Workgroup et al., *CPT Pharmacometrics Syst Pharmacol.* 2016;5(3):93-122

Discussion

- A flowchart for systematic evaluation of assumptions is proposed
- Application to top-down (and bottom-up) models
- The next step:
 - Apply the flowchart to other settings
 - To fully assess its applicability and practicality in assumption evaluation
 - A web-based application / package in a software can be introduced to help modellers to evaluate assumptions comprehensively and efficiently
