Real-World Tumor Dynamics - objectives

How can RWD inform anticancer treatment decisions?

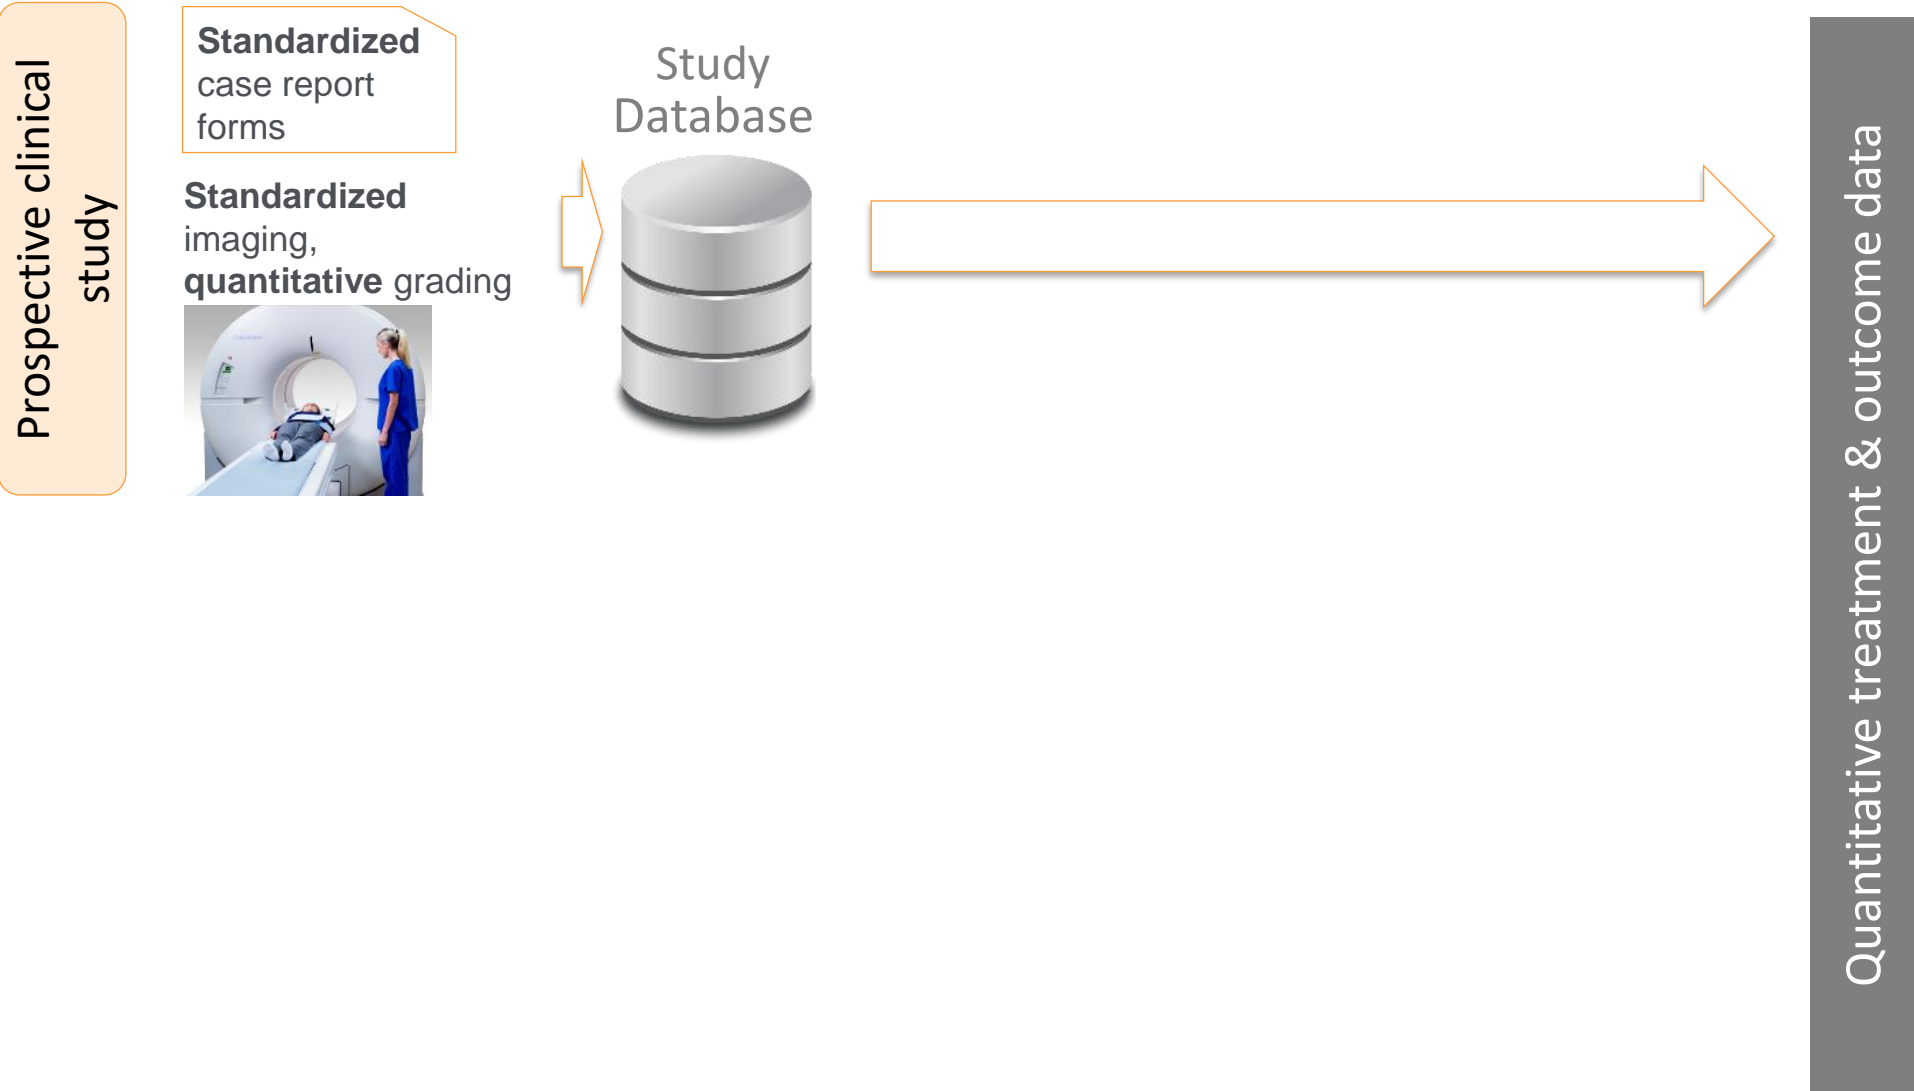

Semi-automated pipeline for **collection and curation** of RWD¹

Population tumor growth inhibition model in advanced cutaneous melanoma patients receiving ICIs

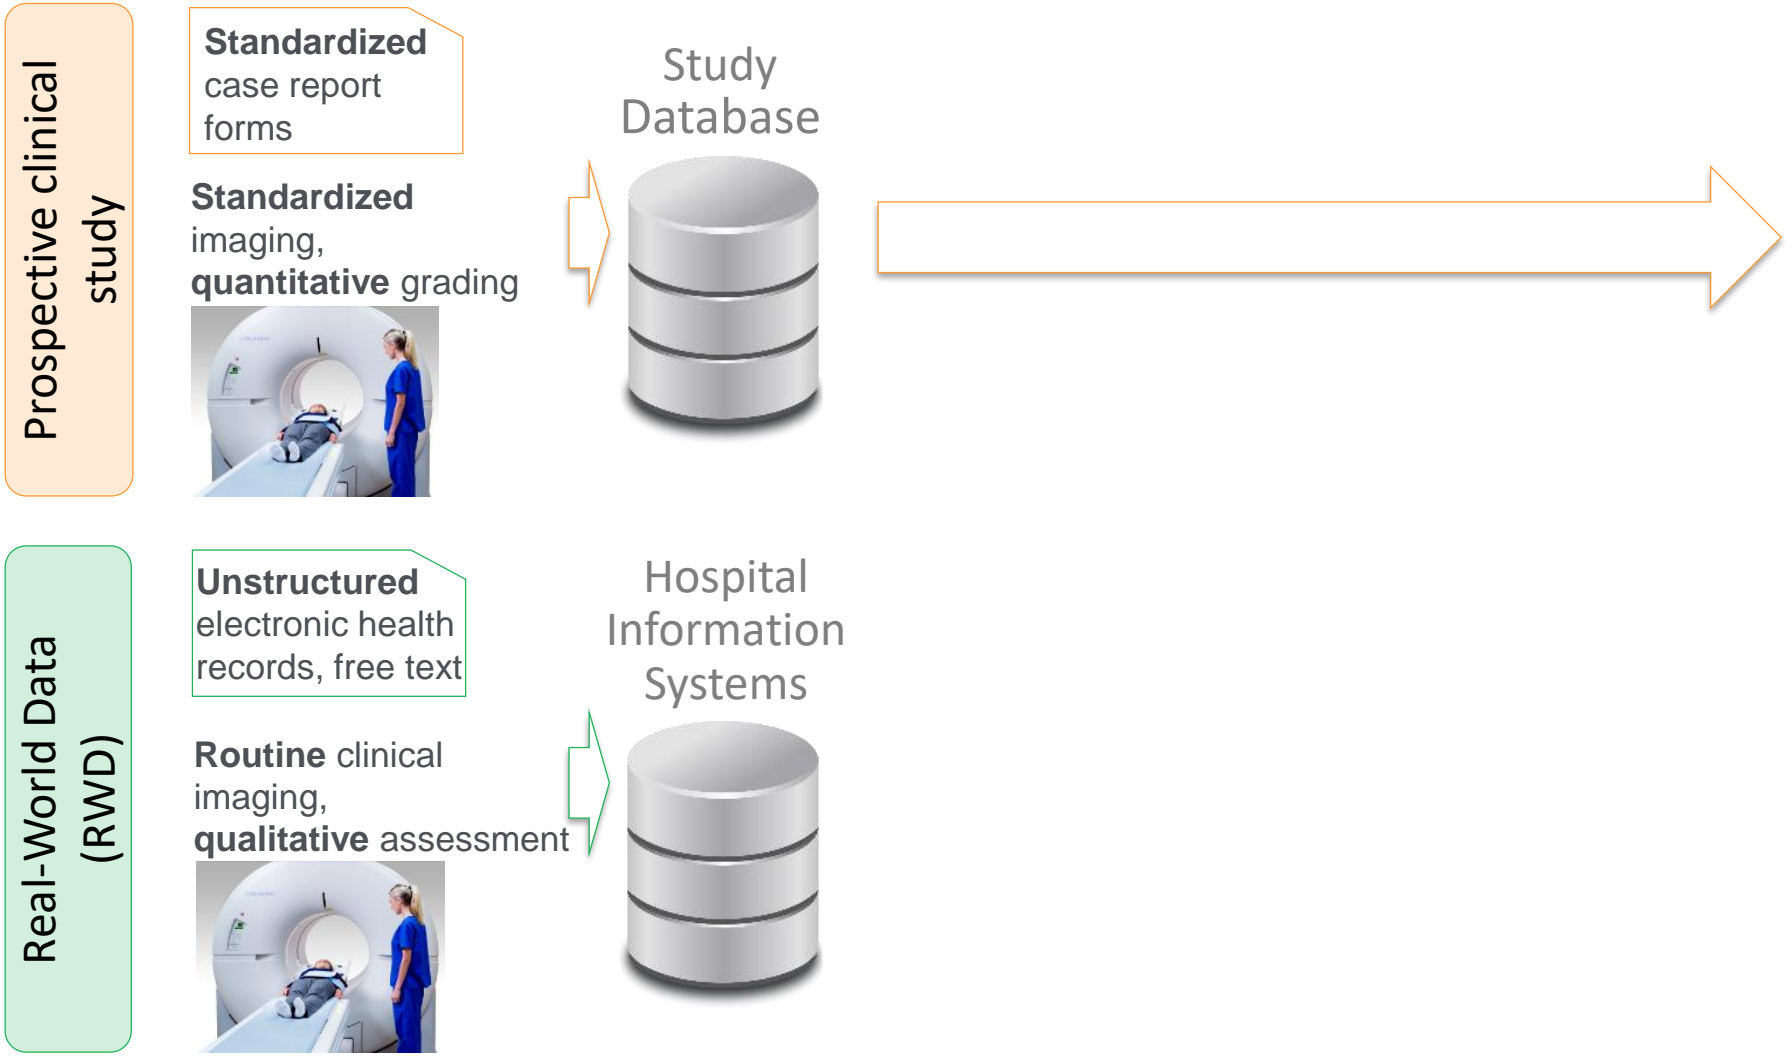

RWD collection is challenging and requires prior data curation steps

Longitudinal modeling of tumor volume

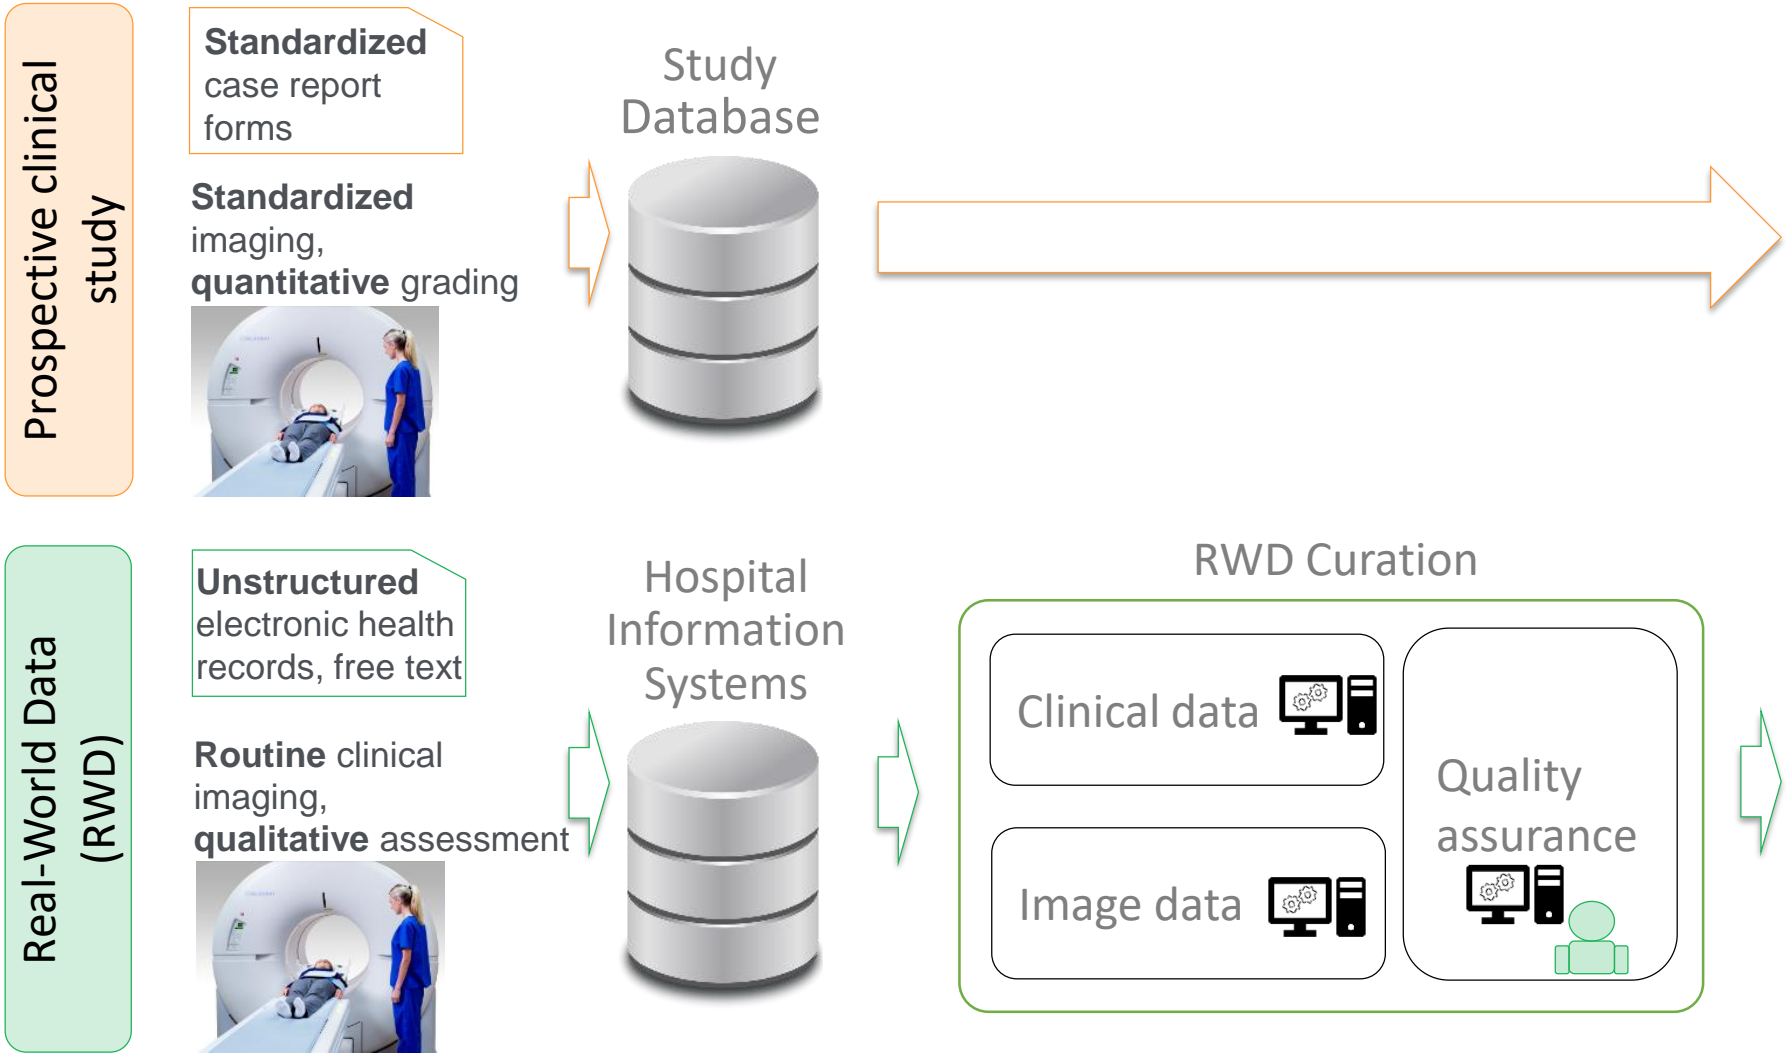

RWD collection is challenging and requires prior data curation steps

Longitudinal modeling of tumor volume

RWD collection is challenging and requires prior data curation steps

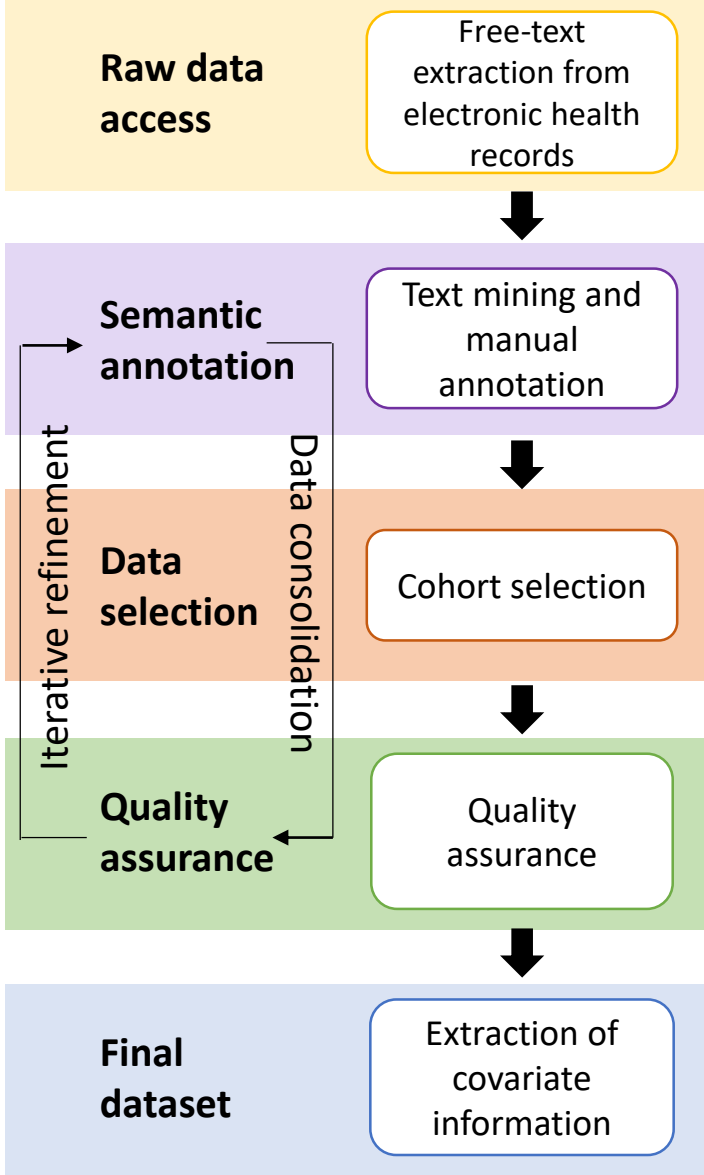

Longitudinal modeling of tumor volume

Quantitative treatment & outcome data

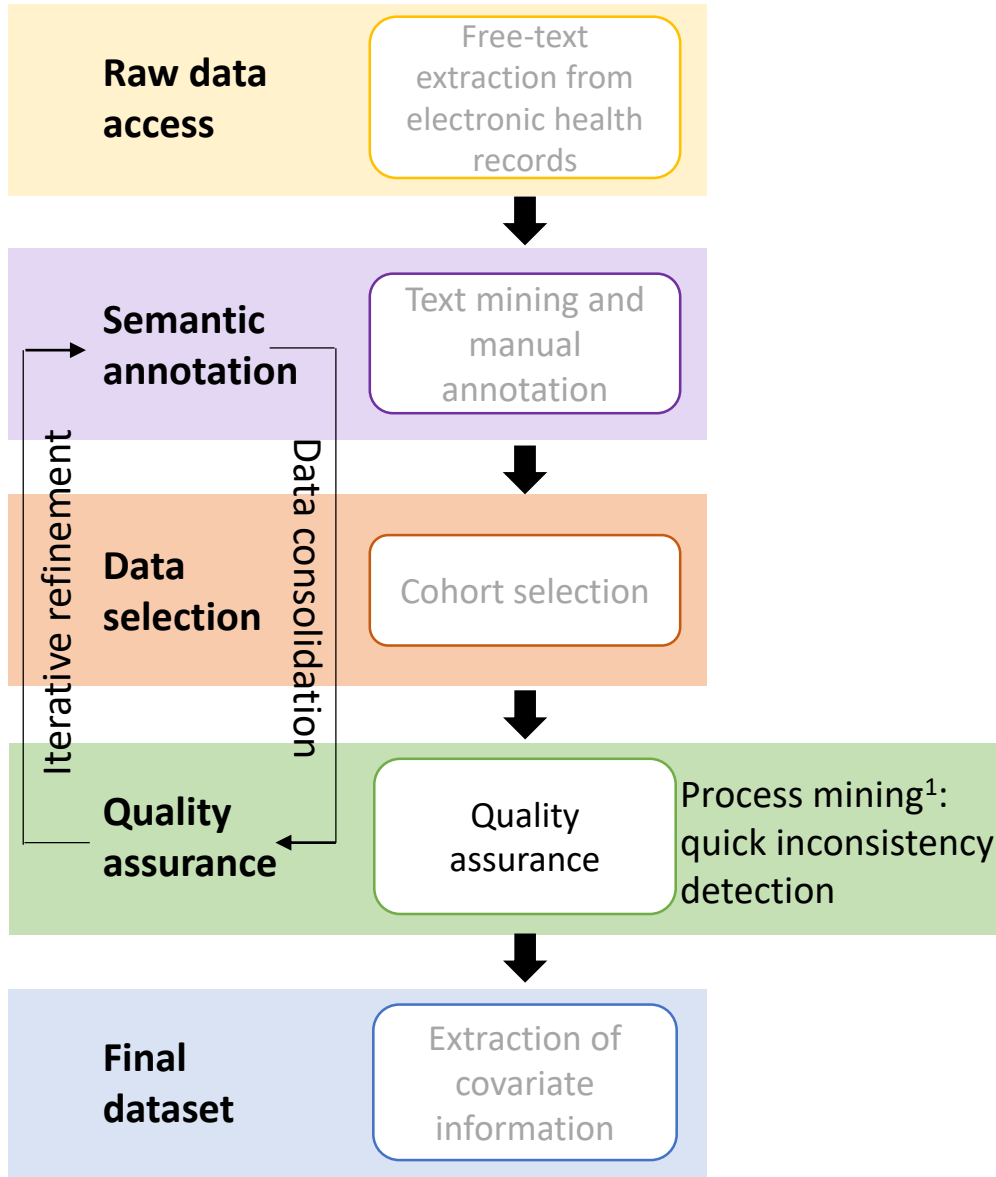

Clinical data were extracted from electronic health records, annotated and assessed for quality

Clinical data

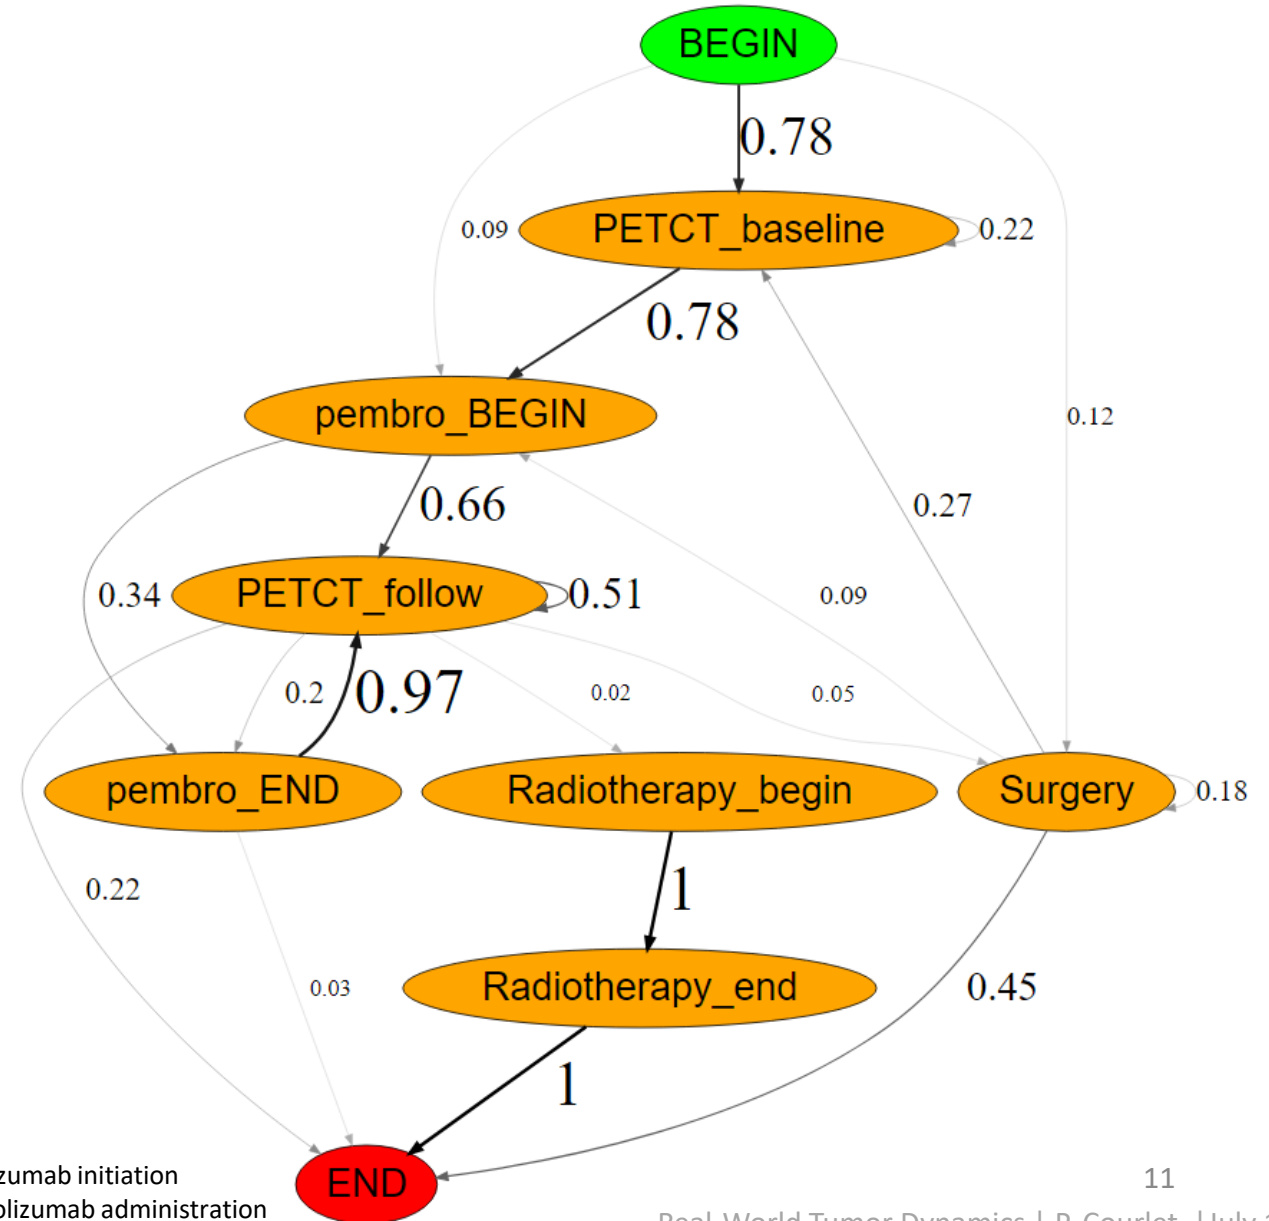

Process mining was employed as quality assurance step to validate the extracted data

Clinical data

Example of patients workflow

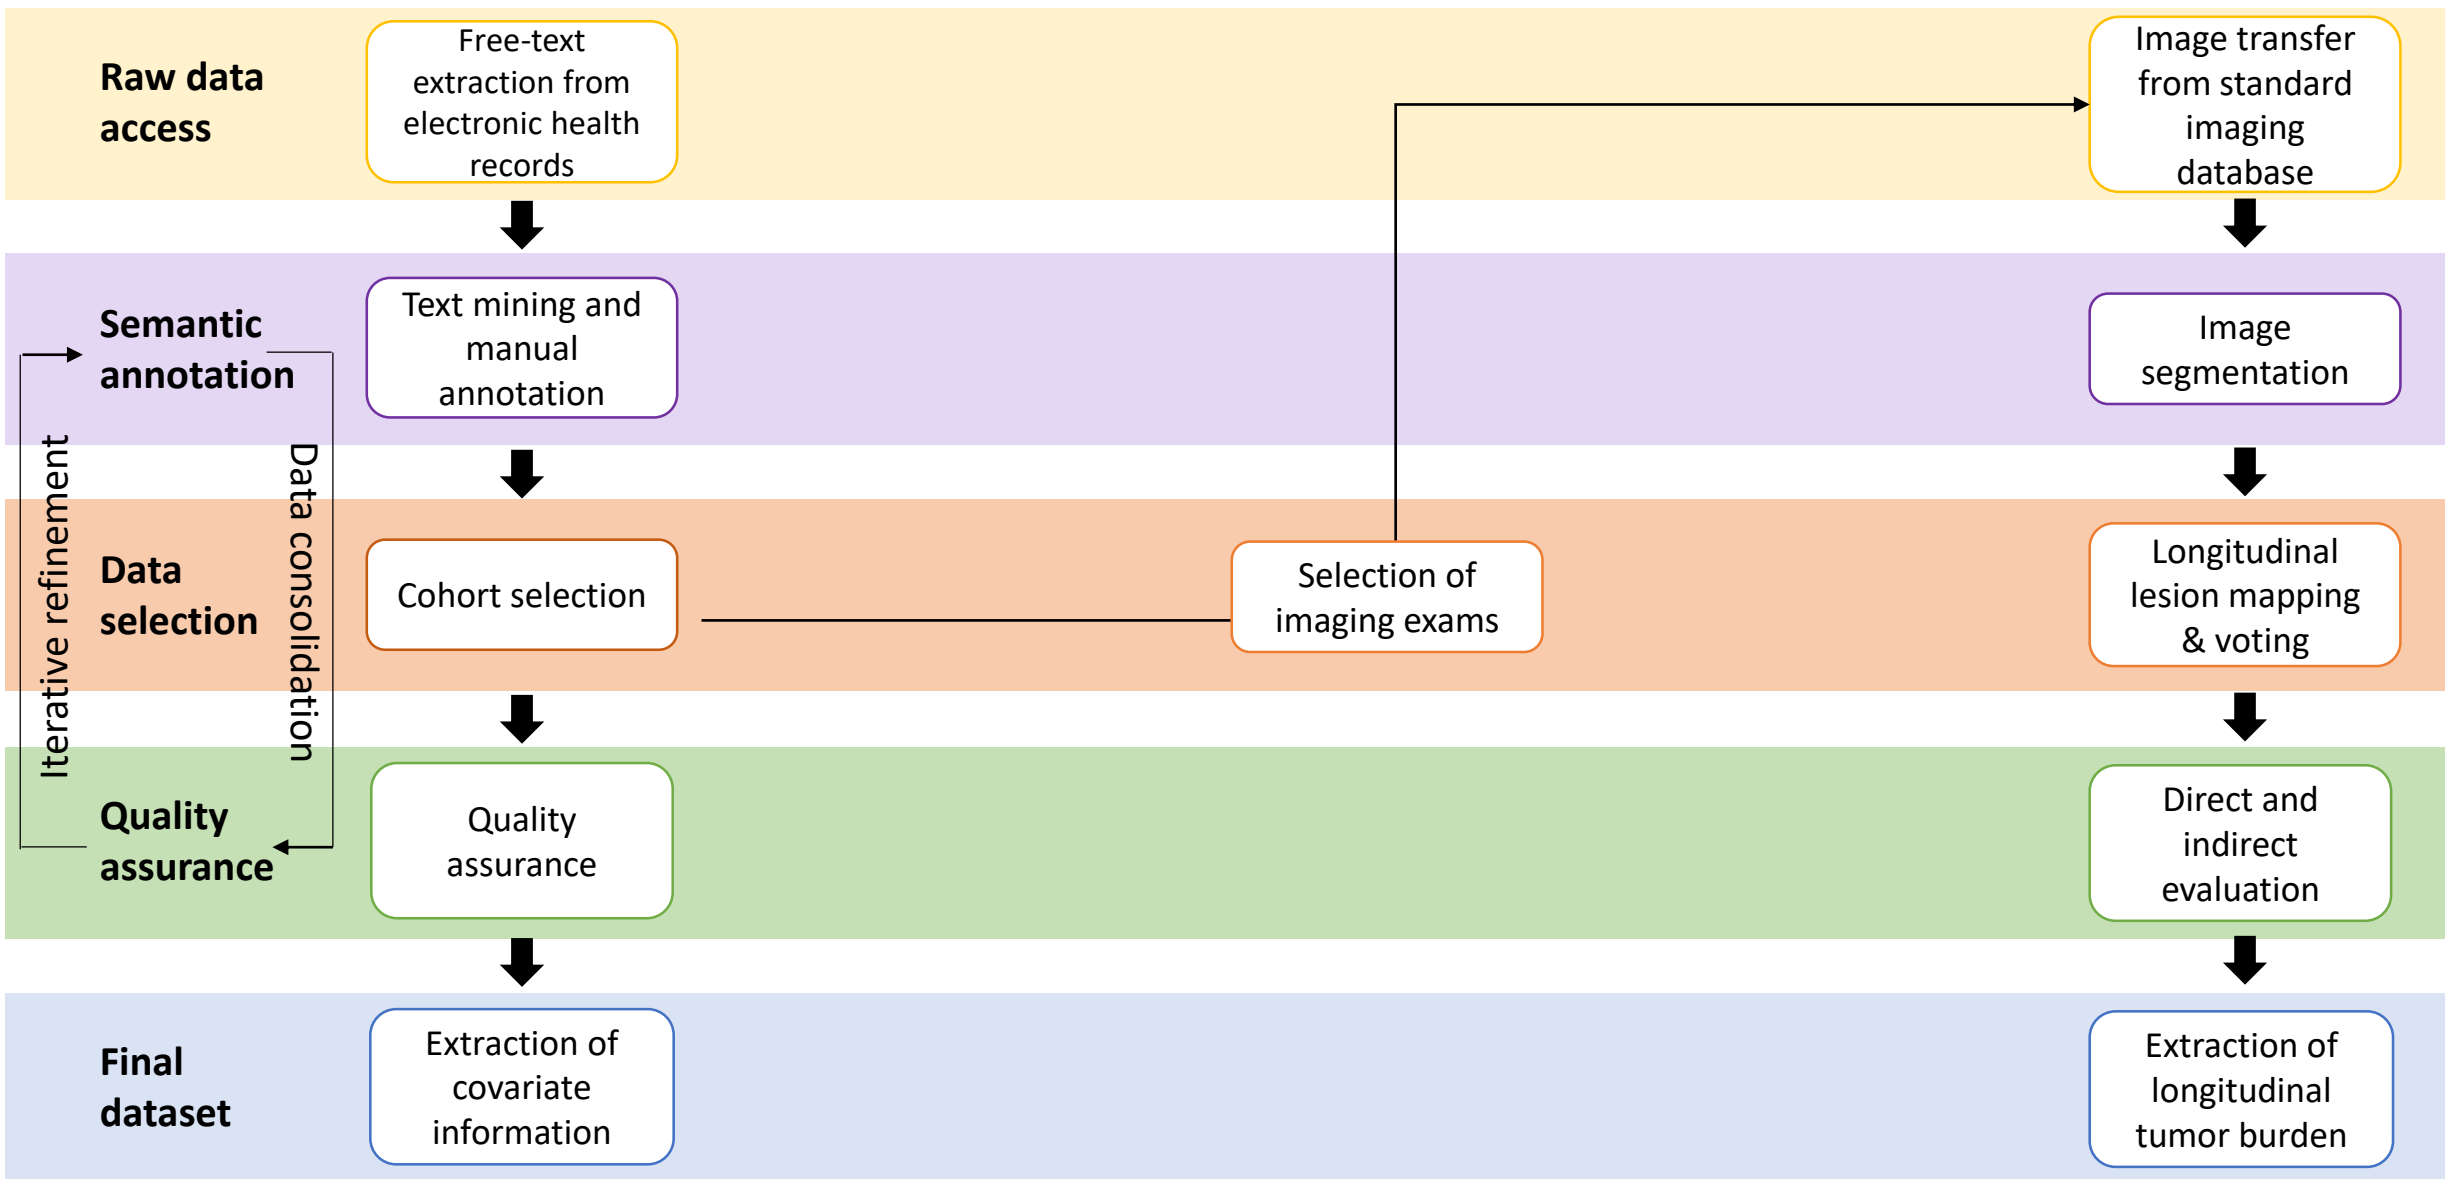

¹Gatta R. 2017.

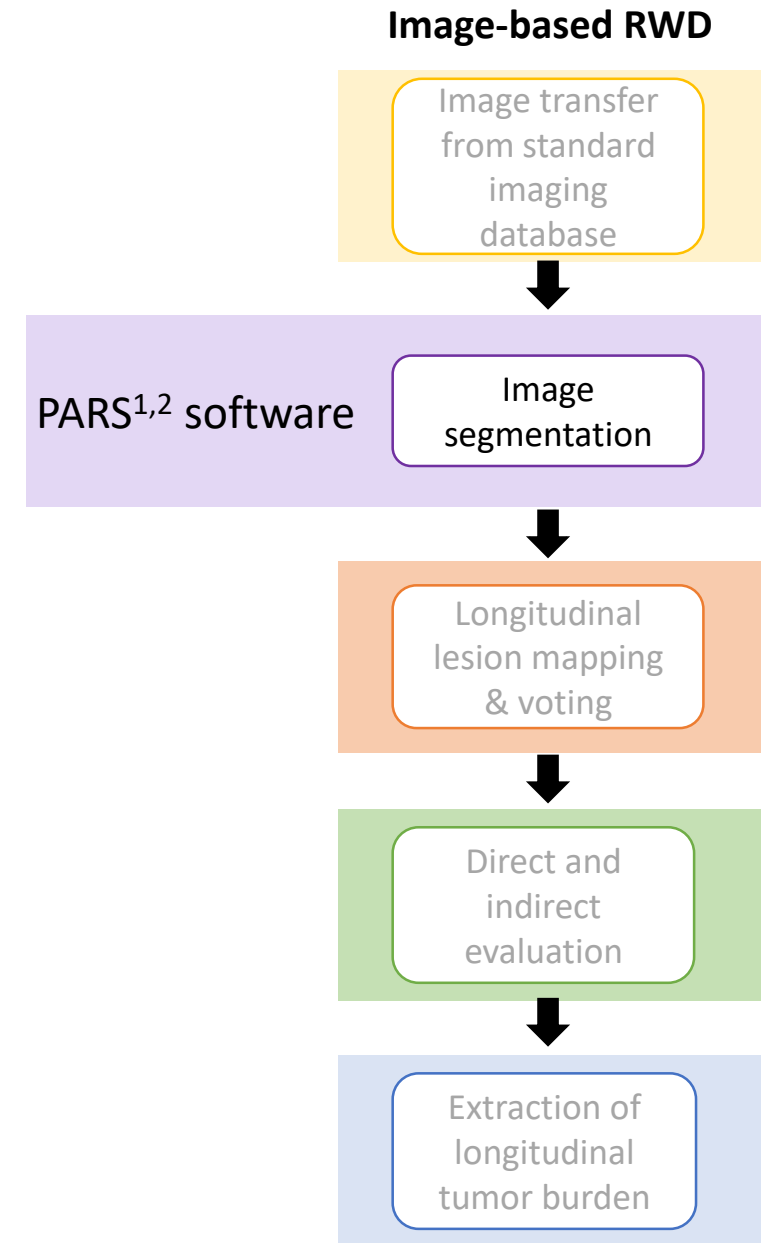

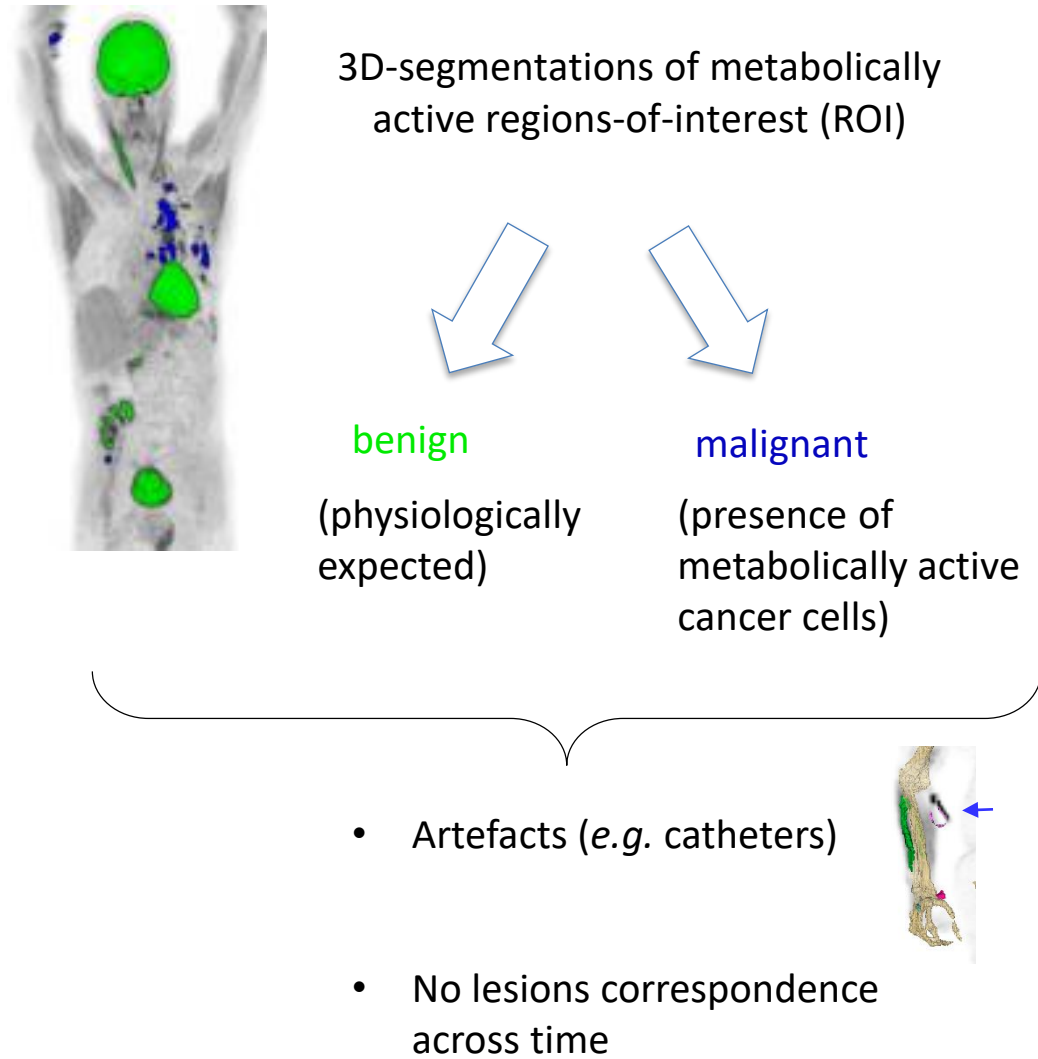

Images-related data were then retrieved and analyzed

Clinical data

Image-based RWD

PET/CT imaging data were segmented by employing Deep learning methods

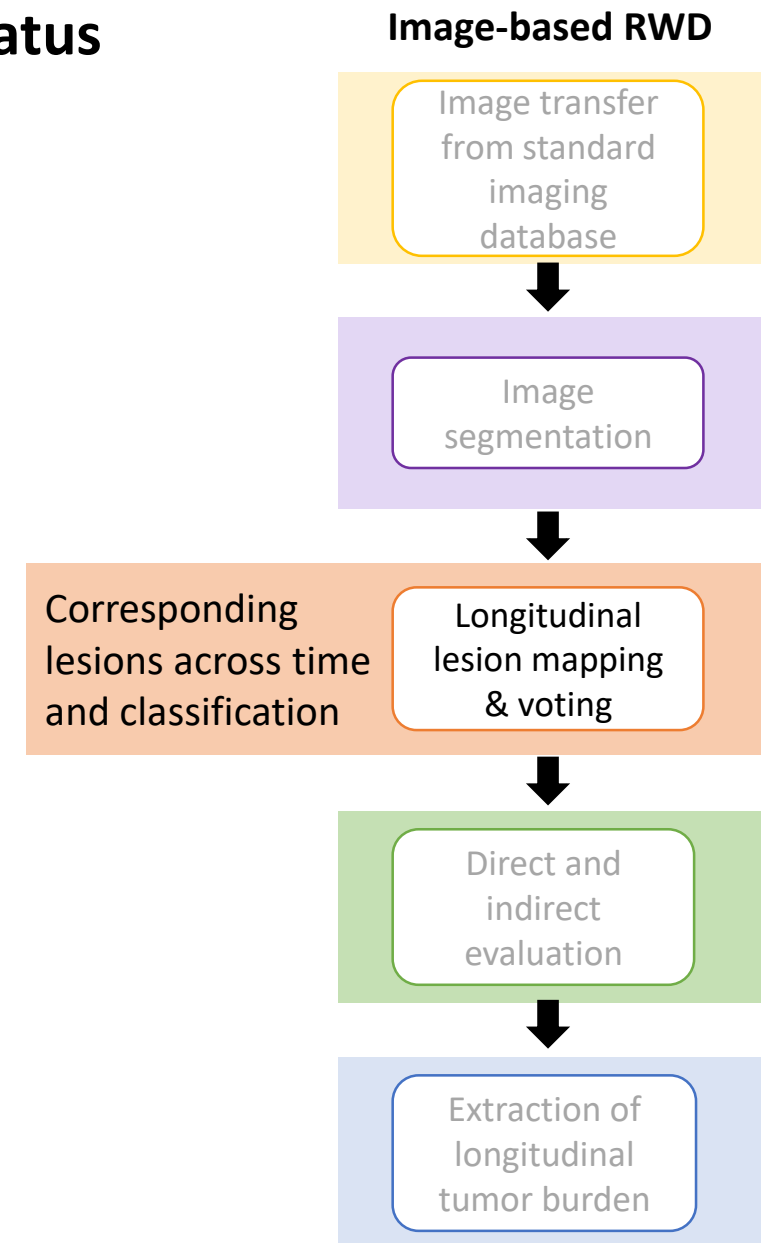

Trajectories of individual tumor lesions were reconstructed through automated longitudinal mapping and majority voting of the status

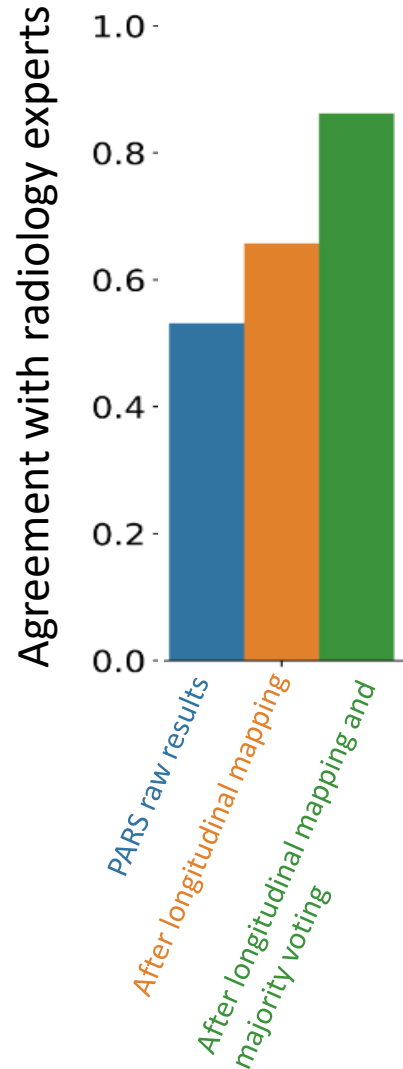

- Same location → *same* tumor lesion

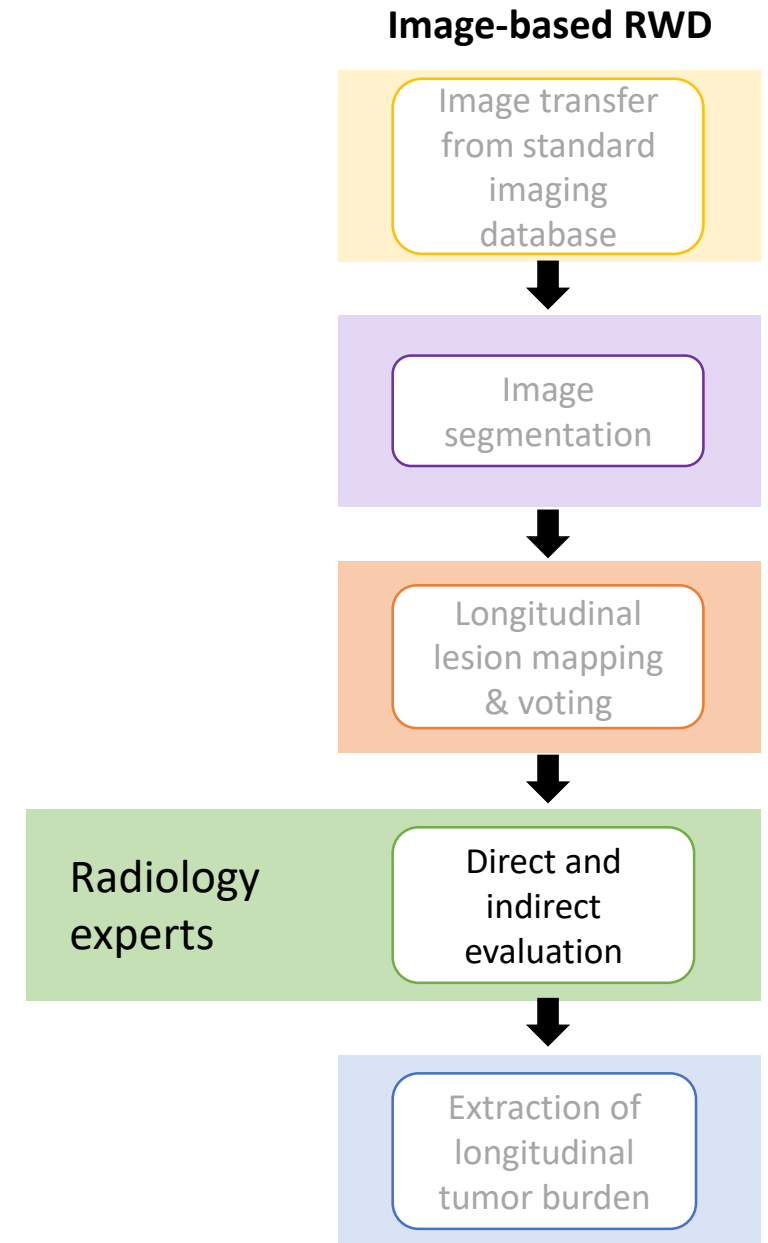

- Malignancy status assigned to the entire lesion trajectory

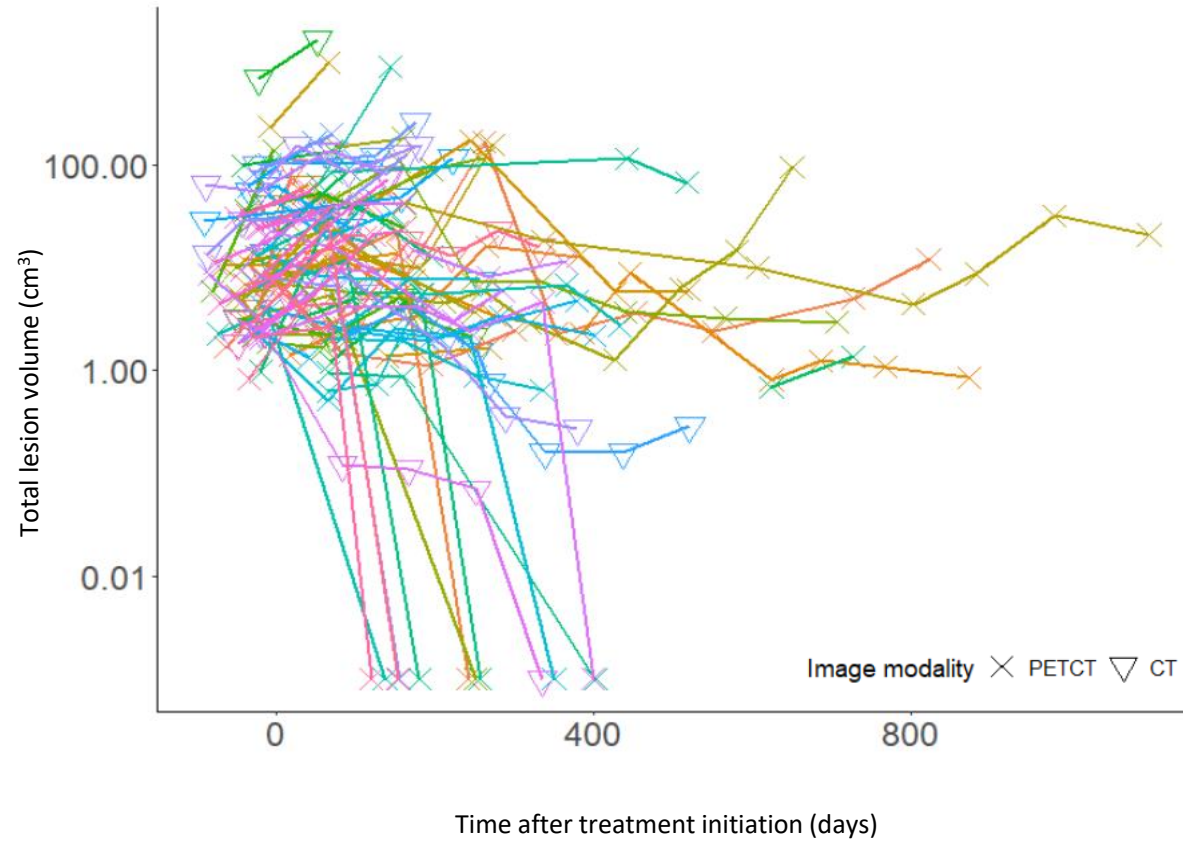

Our methods greatly improved data quality

Improvement in the consistency of image-derived data compared to isolated segmentation results.

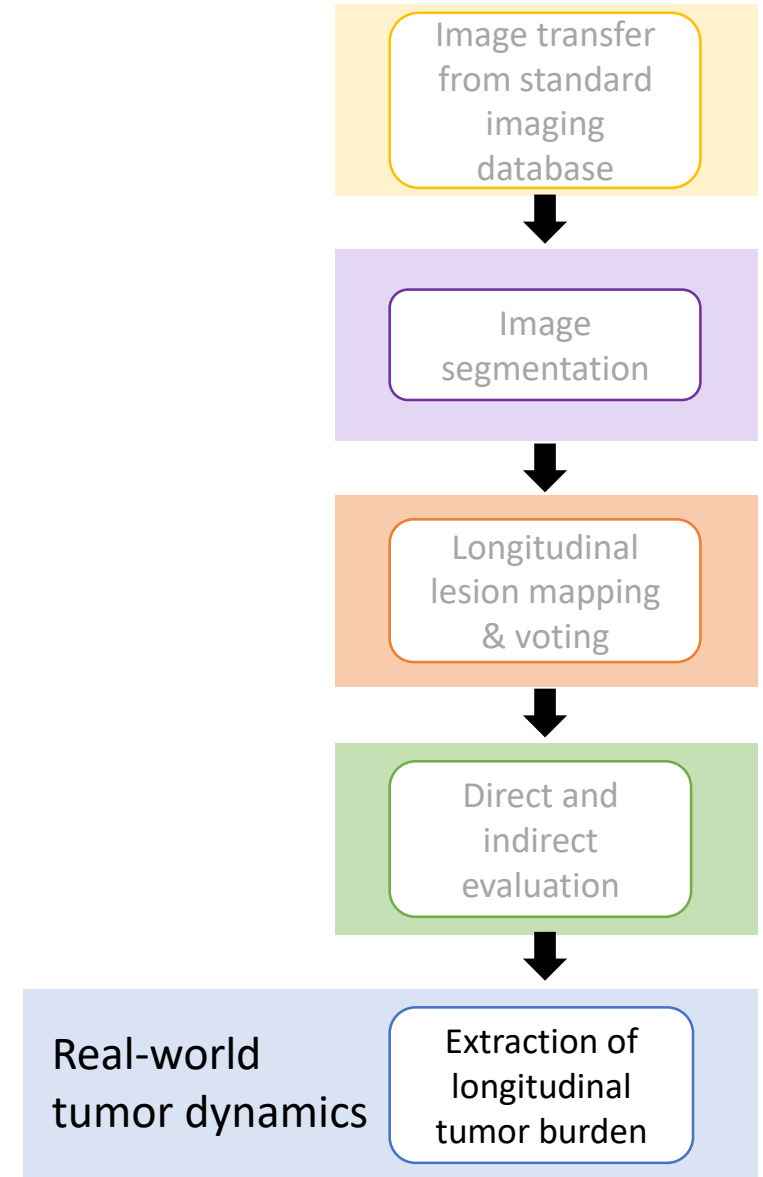

Tumor profiles over time were derived from 91 melanoma patients receiving ICIs

Treatments { Ipilimumab
Nivolumab
Pembrolizumab

Image-based RWD

A model describing longitudinal tumor volumes was developed by assessing different system- and treatment-related assumptions

Tumor growth model:

Exponential tumor growth with a rate constant retrieved from literature¹

Treatment effect (no PK data):

- KPD model²
- Drug dose
- Treatment ON/OFF

Log-kill hypothesis:

- One killing rate/drug
- $k_{\text{kill,nivolumab}} = k_{\text{kill,pembrolizumab}}$ ³
- $k_{\text{kill,nivolumab}} = k_{\text{kill,pembrolizumab}} = k_{\text{kill,ipilimumab}}$

A model describing longitudinal tumor volumes was developed by assessing different system- and treatment-related assumptions

Tumor growth model:
Exponential tumor growth with a rate constant retrieved from literature¹

Treatment effect (no PK data):

- KPD model²
- Drug dose
- Treatment ON/OFF ←

Log-kill hypothesis:

- One killing rate/drug
- $k_{kill,nivolumab} = k_{kill,pembrolizumab}$ ³
- $k_{kill,nivolumab} = k_{kill,pembrolizumab} = k_{kill,ipilimumab}$ ← Principle of parsimony

OFF treatment: $dTV/dt = k_{growth} \times TV$

ON treatment: $dTV/dt = k_{growth} \times TV - k_{kill} \times TV$

Similar performances when comparing simple and more complex models (precision, BIC, GOF, VPCs)

Model simplification

Multi-dimensional covariate assessment enabled by machine learning approaches

16 clinical covariates

(demographics, disease status, lab values, genomics)

Radiomics features

Radiomics features

Quantitative description of imaging ROI

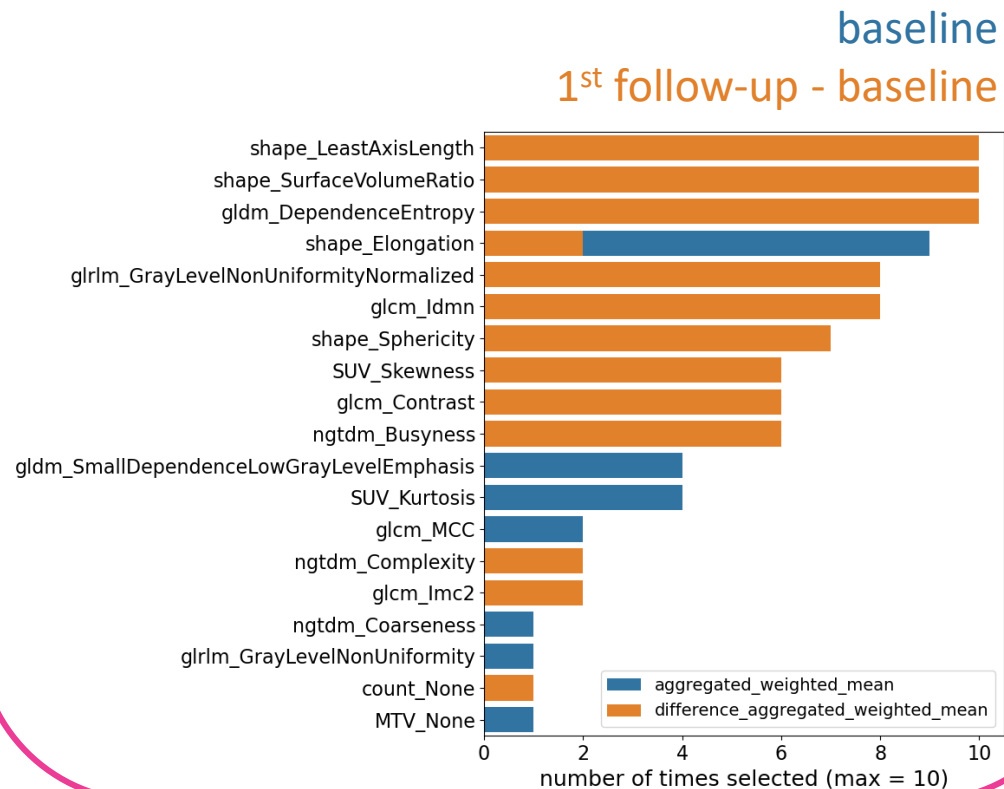

>100 features per lesion & timepoint

~230 features per patient

ML-based radiomics feature pre-selection³

Example for tumor growth rate constant

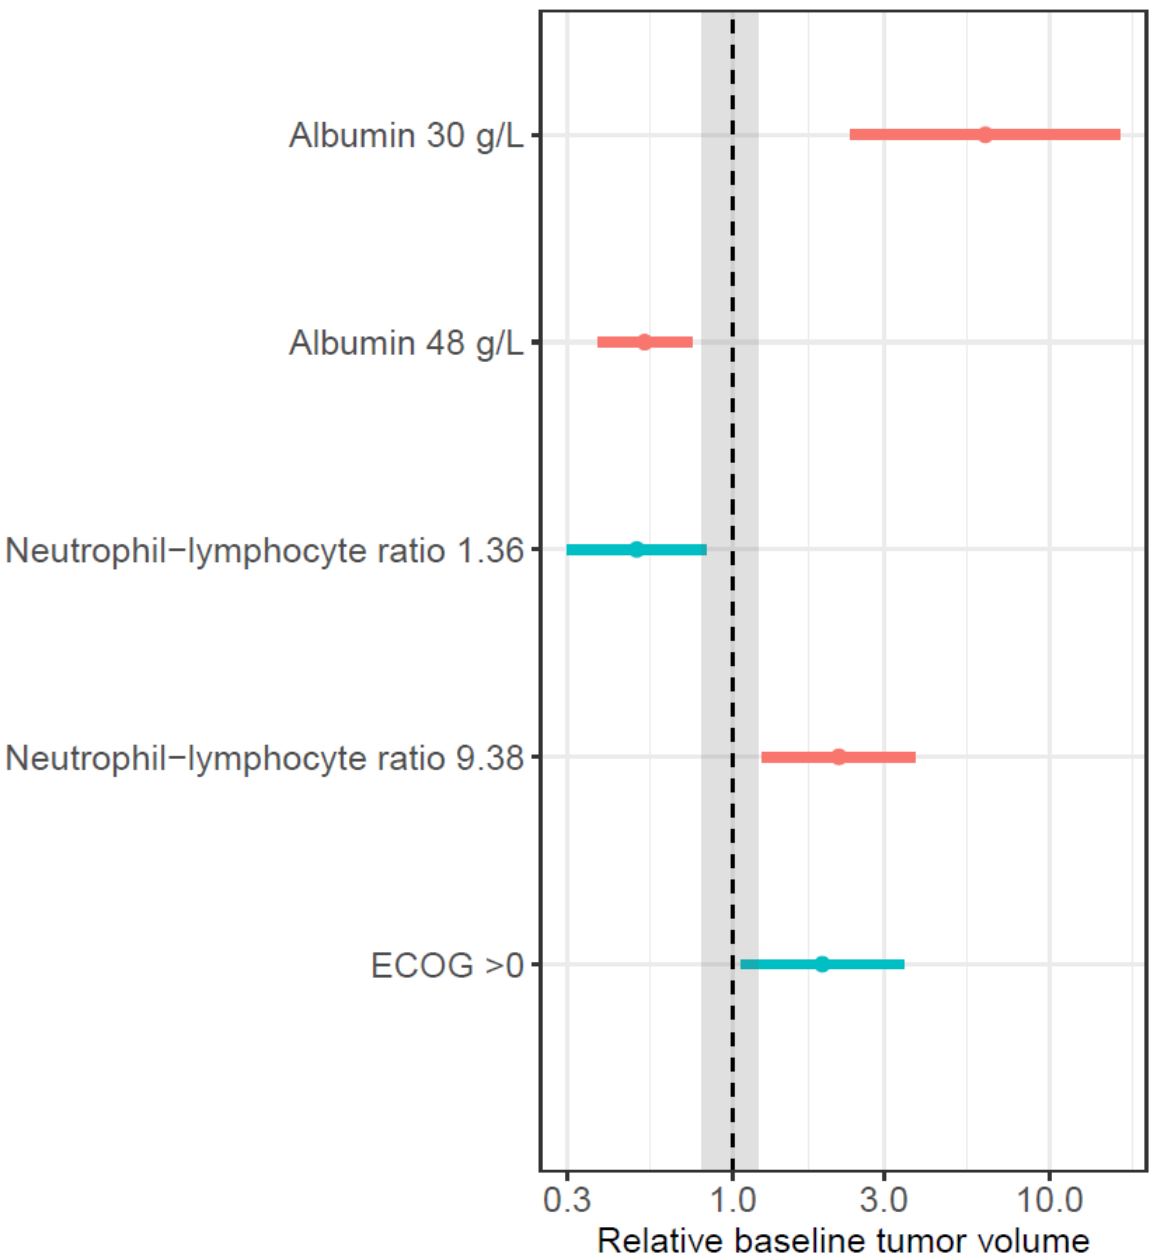

Standard PMX covariate assessment_{1,2}

¹Prague M. 2022.

²Ayral G. 2021.

³Terranova N. 2021.

Clinically relevant covariate effects were identified on baseline tumor volume

Influence of factors related to cachexia, inflammation and advanced disease identified on TV_0

24% of variability on TV_0 explained by covariates

Interpretation

- Change >20%
- Potential change >20%

Potential effect of NRAS mutation on k_{growth}

Some radiomics features were significantly associated with model parameters

k_{growth}

Delta Shape Elongation

Baseline image

1st follow-up image

Higher k_{growth}

TV_0

Gray Level Non Uniformity

Homogeneity

Lower TV_0

Preliminary
results (38 patients)

Multiple
imputation

Clinical
relevance

Conclusion: Real-world tumor dynamics data collected using our newly developed semi-automated pipeline were successfully described by a TGI model

Semi automated pipeline

Data quality supports population-based analyses

Easily applicable to other cancer subtypes and therapies

Modeling and multi-dimensional covariates

Tumor dynamics successfully described in our RW population

Identification of sources of variability

Multi-dimensional analysis of clinical and image-based RWD has the potential to advance precision oncology towards more individualized treatment solutions
