INTRODUCTION

The full Bayesian approach has been suggested as a suitable method for population pharmacokinetic/pharmacodynamic (PK/PD) modeling. However, to this day, published examples of its application to real population PK-PD problems are limited due to time/labor intensive, and difficulty in achieving model convergences. Monte-Carlo parametric expectation maximization (MCPM) is a two-stage hierarchical method that uses Monte-Carlo integration methods for obtaining exact likelihood function and has been used successfully in analyzing complex population PK/PD data.

The S-ADAPT program uses the MCPM method to provide initial parameters for the three-stage analysis provided in WINBUGS. S-ADAPT also provides a command that systematically packages PK/PD data and the MCPM results into the BLACKBOX/WINBUGS environment to allow easier Bayesian analysis of PK/PD models.

OBJECTIVES

To develop a systematical approach to bridge the two-stage MCPM algorithm and full Bayesian three-stage hierarchical model in complex population PK/PD analysis

METHODS

DATA

Thirty-one patients with advanced solid malignancies were treated with cisplatin 1-hour intravenous infusion followed by troxacitabine 30-minute intravenous infusion on Day 1 every 28 days at the following cisplatin/troxacitabine (mg/m²) dose levels: 50/4.8, 75/4.8, 50/6.4, 75/6.4 and 75/8.0. PK samples were obtained during cycle 1 before dosing and at 0, 0.25, 0.5, 1, 2, 4, 8, 24, 48, 72, and 168 hours after the end of the 30 minute intravenous infusion of troxacitabine. The absolute neutrophil count (ANC) was obtained during the documented routine clinical follow-up.

PKPD MODEL

- A three-compartment linear PK model was used to describe the troxacitabine concentration-time profile. The PD model was based on a drug-sensitive progenitor cell compartment, linked to the peripheral blood compartment, through three transition compartments representing the maturation chain in the bone marrow. The model included a feedback mechanism to capture the rebound phenomena. The troxacitabine affected the proliferation of sensitive progenitor cells through an inhibitory sigmoidal Emax model.
- The schematic and differential equations of the PK/PD model for troxacitabine was as follows :

PK

PD

$$\begin{aligned} \frac{dX_1}{dt} &= -\frac{CL + CL_d + CL_{d1}}{V_c} * X_1 + \frac{CL_d}{V_2} * X_2 + \frac{CL_{d1}}{V_3} * X_3 \\ \frac{dX_2}{dt} &= \frac{CL_d}{V_c} * X_1 - \frac{CL_d}{V_2} * X_2 \\ \frac{dX_3}{dt} &= \frac{CL_{d1}}{V_c} * X_1 - \frac{CL_{d1}}{V_3} * X_3 \\ \frac{dX_4}{dt} &= k_{syn} * X_4 * \left(\frac{Baseline}{X_N} \right)^0 * \left[1 - \frac{E_{max} * \left(\frac{X_1}{V_c} \right)^{\gamma}}{km^{\gamma} + \left(\frac{X_1}{V_c} \right)^{\gamma}} \right] - kt * X_4 \\ \frac{dX_5}{dt} &= kt * (X_4 - X_5); \quad \frac{dX_6}{dt} = kt * (X_5 - X_6); \quad \frac{dX_7}{dt} = kt * (X_6 - X_7) \\ \frac{dX_N}{dt} &= kt * (X_7 - X_N) \end{aligned}$$

- Interindividual variability was assumed to be log-normally distributed and was fitted by use of an exponential model. Proportional error model was used to describe the intraindividual variability for both PK and PD.
- First, the PKPD model was developed using the MCPM algorithm implemented in S-ADAPT and fit simultaneously to the PK/PD data. The S-ADAPT program then automatically generated several files (including dose/dosing time, observations, priors, initial parameters, and model template files) needed for the BLACKBOX/WINBUGS program for full Bayesian analysis. The individual and population parameters estimated from MCPM algorithm served as initial values for the WINBUGS program, and the PKPD data were analyzed simultaneously.
- In S-ADAPT, the differential equations were coded in Fortran. In BLACKBOX/WINBUGS, the differential equations were programmed in component Pascal using the WBDIFF tool as a template environment.

RESULTS AND CONCLUSIONS

FIGURE 1. PKPD MODEL FILE FOR WINBUGS ANALYSIS (Template model file provided by S-ADAPT)

```
